

Synopsis

The 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals (SDGs), adopted by the United Nations (UN) in September 2015, is the world's roadmap for achieving sustainable development in this decade. The European Union (EU) has fully committed itself to delivering on the 2030 Agenda, and the SDGs form an intrinsic part of the [European Commission's work programme](#) and the [Political Guidelines](#) of Commission's President Ursula von der Leyen (¹). In this context, the EU will also present its first Voluntary Review on the implementation of the 2030 Agenda at the United Nations' (UN) High-Level Political Forum in July 2023.

Monitoring is an essential component in realising the 2030 Agenda's vision, both globally and in the EU, by assessing and visualising the progress made so far towards the 17 SDGs. Since 2017, Eurostat has been preparing annual reports monitoring the progress towards the SDGs in the EU context. This 2023 edition is the seventh report in this series, analysing the EU's progress towards the goals based on the [official EU SDG indicator set](#).

Reflecting the timespan of the 2030 Agenda, this report aims to present an objective assessment of whether the EU — according to the selected indicators — has progressed towards the SDGs over the past 15-year period. Additionally, short-

term trends over the most recent five-year period of available data are presented to provide an indication of whether a trend has been persistent or has shown a turnaround at a certain point in time. The report consequently focuses on the trends over the past five- and 15-year periods. Given the time lag of the available data, these mainly refer to the periods up to 2021 or 2022. While the impacts of the COVID-19 pandemic are thus largely visible for most of the indicators, more recent developments such as those caused by Russia's military aggression against Ukraine are only partly reflected in the available data.

How has the EU progressed towards the SDGs?

This synopsis chapter provides a statistical overview of progress towards the SDGs in the EU. Because a long-term assessment is not possible for a number of indicators due to limited data availability, the progress at goal-level presented in this chapter is assessed over the most recent five-year period ('short-term') based on the EU SDG indicators. The figure on the next page shows the pace at which the EU has progressed towards each of the 17 goals over this short-term period according to the selected indicators. The method for assessing indicator trends and aggregating them at the goal-level is explained in Annex I.

Over the five-year period assessed, the EU has made significant progress towards ensuring decent work and economic growth (SDG 8) and reducing poverty (SDG 1), as well as towards

improving gender equality (SDG 5). Good progress has also been achieved towards reducing inequalities (SDG 10), ensuring quality education (SDG 4) and fostering peace and personal security within the EU's territory and improving access to justice and trust in institutions (SDG 16). The EU has also seen good progress towards the goals on health and well-being (SDG 3), despite setbacks caused by the COVID-19 pandemic, and on innovation and infrastructure (SDG 9).

Progress towards the remaining goals was less significant, as shown in the figure on the next page. Overall, the goal-level assessment in this year's SDG monitoring report shows that the EU has progressed strongly towards many socio-economic goals over the most recent five-year period of available data, while trends in the environmental domain have been less favourable.

More progress is expected for three goals — climate action (SDG 13), life on land (SDG 15) and global partnerships (SDG 17). Regarding climate action (SDG 13), the EU has set ambitious and unparalleled climate targets for 2030, which, as compared with past trends, will require more efforts. The EU has already put in place the policy measures to deliver these additional efforts, notably via the 'Fit for 55' package. In the area of energy, the EU has also set more ambitious targets for 2030 ⁽²⁾. This implies that stronger progress is expected to be visible in the coming years in the area of energy efficiency and renewable energies in the EU. Concerning life on land (SDG 15), even though terrestrial protected areas have increased since 2013, additional efforts are needed to reverse the degradation of ecosystems. Regarding partnerships for the goals (SDG 17), the trend partially reflects cyclical effects, notably the increase in public debt resulting from the COVID-19 crisis.

For each of the goals, the following section provides a brief overview of the main indicator trends standing behind the goal-level assessment. The goals are presented in order of aggregated indicator trend assessments, from best to worst.

Summary at goal level

SDG 8 'Decent work and economic growth'

shows continued signs of recovery after the pandemic's impact on the economy and the labour market, with further progress in

2022 despite the impacts of Russia's military aggression against Ukraine. After the economic recovery in 2021, GDP per capita continued to grow strongly in 2022, by 3.3%, and investment reached a new peak of 23.2% of GDP in that year. This favourable development is also reflected in the labour market, with the EU's employment rate reaching a new record high of 74.6% in 2022. Similarly, both the EU's long-term unemployment rate and the share of young people neither in employment nor in education and training (NEET) fell to new record lows in 2022. The EU thus seems well on track to meeting its respective 2030 targets for employment and NEET rates. In the area of decent work, both the incidence of fatal work accidents and the share of 'working poor' have seen clearly favourable developments in the time period assessed. The EU's material footprint, however, had been rising until 2019, and most recent data still only reflect the reduced economic activity in 2020. Data on domestic material consumption suggest resource use had risen to almost pre-pandemic levels in 2021 alongside the economic recovery.

The EU's situation regarding **SDG 1 'No poverty'** is characterised by considerable improvements in all poverty dimensions monitored in this report as well as an increasing

share of people being able to meet their basic needs. Most of these improvements took place in the period up to 2019, while poverty rates have remained rather stable in 2020 and 2021 ⁽³⁾. In the area of multidimensional poverty, trends in the five-year period assessed show that fewer people were affected by monetary poverty, suffered from severe material and social deprivation or lived in (quasi-)jobless households. This resulted in a marked improvement concerning the overall risk of poverty or social exclusion across the EU, even

Overview of EU progress towards the SDGs over the past 5 years, 2023

(Data mainly refer to 2016–2021 or 2017–2022)

though stronger progress will be necessary to meet the target of lifting at least 15 million people out of poverty or social exclusion by 2030. In the area of basic needs, the share of people overburdened by their housing costs or facing severe housing deprivation has fallen since 2015. Additionally, the proportion of people reporting unmet needs for medical care was lower in 2021 than five years earlier, even though the rate has risen slightly since 2017.

SDG 5 'Gender equality'

shows a quite favourable picture in most of the areas monitored. Regarding employment, women's hourly earnings are catching up with those of men,

and the gap between men and women who are outside the labour force due to caring responsibilities has narrowed since 2017. Similarly, the gender employment gap has narrowed since 2017, even though stronger progress will be necessary for the EU to meet its target of halving this gap by 2030. Women also continue to increasingly occupy leadership positions, as shown by considerable growth in both the shares of women in national parliaments and in senior management positions of the largest listed companies. Despite these improvements, however, the gender situation remains far from parity in both areas. In the area of education, the gender gap is reversed, with more young women than men attaining secondary and tertiary education. While this gap has slightly narrowed since 2017 for early school leaving, men continue to fall further behind women in terms of tertiary educational attainment.

Developments in the area of **SDG 10 'Reduced inequalities'** reveal a quite favourable picture over the most recent five-year period of available data. Income

inequalities within countries improved between 2016 and 2021, as shown by the narrowing of the income gaps between the richer and the poorer population groups. Similarly, the depth of poverty ⁽⁴⁾ reduced, and the poverty gap between rural and urban areas narrowed in the EU. Data on

economic disparities between EU countries also paint a favourable picture, showing a continued convergence of Member States in terms of GDP per capita and household income, even though the trend for GDP per capita was temporarily interrupted by the repercussions of the COVID-19 pandemic. The labour market integration of migrants from outside the EU largely improved alongside the economic recovery in 2021 and 2022. The gap between non-EU citizens and EU home-country nationals has narrowed for monetary poverty (compared with 2016) as well as for the employment rate and for young people neither in employment nor in education and training (NEET), while it has slightly widened for the rate of early school leavers (all compared with 2017).

SDG 4 'Quality education' is

characterised by mostly favourable developments over the five-year period assessed.

Regarding participation in education, the EU is well on

track to meet its 2030 targets for early leavers from education and training and tertiary educational attainment. Adult learning has also increased since 2017, showing particularly strong growth in 2022. However, the share of children participating in early childhood education has grown slowly in the EU since 2015, and stronger progress will be necessary in the coming years to meet the respective 2030 target. Moreover, trends have been quite unfavourable for educational outcomes. The proportion of low achieving pupils in reading, maths and science as measured in the OECD's PISA study increased between 2015 and 2018, moving the EU further away from its target of reducing these shares to 15 % by 2030. In addition, the share of adults with at least basic digital skills stood below 55 % in 2021 and thus remains far from the target of raising this share to 80 % by 2030.

The EU has continued to make good progress towards **SDG 16 'Peace, justice and strong institutions'**, even though some subjective measures of

citizens' perceptions regarding the EU's and Member States' institutions have

shown recent signs of deterioration. Life in the EU has become safer over the past few years, as deaths due to homicide or assault and the perceived occurrence of crime, violence and vandalism in European neighbourhoods have fallen considerably. Furthermore, government expenditure on law courts has increased. However, the perceived independence of justice systems in Member States deteriorated slightly in 2022. Additionally, the EU's rating in the Corruption Perceptions Index has been stagnating, even though EU countries continue to rank among the least-corrupt globally. Citizens' confidence in the European Parliament and the European Commission has somewhat deteriorated compared with pre-pandemic levels, while the European Central Bank has slightly gained in trust.

3 GOOD HEALTH AND WELL-BEING

The assessment of **SDG 3 'Good health and well-being'** is affected by the impacts of the COVID-19 pandemic. While the EU's healthy life expectancy was on the rise until 2019, it declined

by 0.6 years in 2020, down to 64.0 years. People's self-perceived health also slightly declined in 2021, but remained above pre-pandemic levels. The pandemic's strongest impact is visible in the EU's avoidable mortality rate, which increased considerably in 2020 due to COVID-19 related deaths. Road traffic deaths have also risen in 2021 after the lockdown-induced reduction in mobility patterns, and stronger progress will be necessary for the EU to meet its respective 2030 target. The other causes of mortality monitored in this report — deaths due to HIV, tuberculosis and hepatitis, fatal work accidents and premature deaths due to exposure to fine particulate matter — have not (or to a lesser extent) been affected by the pandemic and continue to show favourable developments. The same is true for most of the health determinants monitored. The share of people suffering from noise disturbance has fallen slightly in recent years, as has the share of smokers. In contrast, the share of obese and overweight people has been growing in the EU. Trends in access to health care are still favourable, even though the share of people reporting unmet needs for medical care has increased slightly since 2017.

9 INDUSTRY, INNOVATION AND INFRASTRUCTURE

SDG 9 'Industry, innovation and infrastructure' is

characterised by favourable trends in most of its indicators, with the main exception of the area of sustainable transport. As

regards R&D and innovation, the EU has seen continued but slow growth in its R&D expenditure (both in absolute terms and in relation to GDP), and stronger efforts will be necessary for the EU to meet its respective 2030 target of dedicating 3% of its GDP to R&D. The remaining indicators on patent applications to the European Patent Office, the share of R&D personnel in the labour force and the share of young people with tertiary education have improved considerably in recent years. As regards the sustainability transformation of the EU's industrial sector, the air emissions intensity of the manufacturing sector — referring to the sector's fine particulate matter emissions relative to its gross value added (GVA) — has improved, and the GVA of the environmental goods and services sector has continued to grow more strongly than the total economy. Developments are mixed in the area of sustainable infrastructure. While both passenger and freight transport have shifted further away from environmentally friendly modes such as buses, trains or inland waterways, the share of households enjoying high-speed internet connections has grown considerably since 2016.

12 RESPONSIBLE CONSUMPTION AND PRODUCTION

Trends concerning **SDG 12 'Responsible consumption and production'** have been

somewhat mixed over the past few years. The EU's material footprint, which estimates the

demand for the global extraction of materials induced by the consumption of goods and services within the EU, had been on the rise until 2019, but fell temporarily in 2020 alongside the reduced economic activity caused by the pandemic. Data on domestic material consumption suggest resource use rose to almost pre-pandemic levels in 2021 following the economic recovery. Similarly, and despite a slight drop in 2020, consumption of hazardous chemicals has grown since 2016. While the average carbon dioxide (CO₂) emissions efficiency of new passenger cars had shown

considerable improvement until 2020, a methodological change in the testing procedure prevents a comparison with the most recent data for 2021 ⁽³⁾. Trends in waste generation and management are also mixed. Similar to the material footprint, total waste generation had been on the rise in the EU until 2018 but fell in 2020, likely as a result of lower economic activity. The EU's circular material use rate has stagnated below 12% over the past few years, meaning the EU is currently not on track to doubling this rate by 2030 relative to 2019. On a positive note, the environmental goods and services sector has continued to outperform other economic sectors in terms of growth in gross value added, and has continued its growing trend even in 2020, the first year of the pandemic in Europe.

The indicators used for monitoring **SDG 11 'Sustainable cities and communities'** show largely favourable developments concerning the quality of life in

cities and communities, whereas the picture is more mixed as regards sustainable mobility and environmental impacts. Trends for severe housing deprivation, premature deaths due to exposure to fine particulate matter as well as the occurrence of crime, violence and vandalism in the neighbourhood have been clearly favourable over the past few years. Additionally, the perceived exposure to noise has slightly decreased. In the area of sustainable mobility, trends have been impacted by changes in mobility patterns due to the COVID-19 pandemic. Road traffic deaths increased in 2021 after reaching a lockdown-induced low in 2020, but remained below pre-pandemic levels. Yet, stronger efforts will be necessary for the EU to meet its respective 2030 target. Additionally, public passenger transport modes (buses and trains) had already been losing shares to cars before the pandemic, and 2020 saw a further strong drop as a result of changed mobility habits due to COVID-19 and related restrictions. Settlement areas have kept spreading, not only in absolute terms but also per capita, meaning that land take has increased faster than the EU population. Additionally, the increase in the EU's recycling rate of municipal waste has slowed in recent years, putting the EU off track to meeting its respective target by 2030.

The EU has made only moderate progress towards **SDG 14 'Life below water'**, due to quite divergent developments in the areas monitored. Trends in marine conservation and

sustainable fisheries are generally favourable. The extent of marine protected areas has grown considerably since 2012, and the EU thus appears on track towards meeting the target of 30% of marine waters being under protection by 2030. However, it needs to be acknowledged that the available data do not provide an indication of the sites' conservation status nor the effectiveness of the protection they offer to species and habitats. Model-based indicators on sustainable fisheries provide an improving picture as regards the trends of fish stock biomass and fishing pressure in EU marine waters, referring to both the North-East Atlantic and the Mediterranean and Black Sea (although the situation in the latter remains less favourable). Trends in the area of ocean health are, however, less positive. Due to the absorption of CO₂ into the world's oceans, the mean surface seawater acidity is continuing to increase, and in 2021 reached another unprecedented high over pre-industrial levels. Moreover, the share of EU marine waters affected by eutrophication has risen strongly in recent years. On a more positive note, the share of coastal bathing sites with excellent water quality has increased slightly in the EU Member States since 2016.

Monitoring **SDG 2 'Zero hunger'** in an EU context focuses on malnutrition, the sustainability of agricultural production and its environmental impacts. Trends

in the area of malnutrition remain unfavourable, with a clear increase in the share of obese people in the EU since 2014. In contrast, trends concerning the viability and sustainability of agricultural production have been favourable over the past five years. The labour productivity of the EU's agricultural sector has improved and public investments in agricultural R&D have increased. In addition, the area under organic farming has grown steadily, although stronger progress will be required to meet the target for 25% of the EU's total farmland to be farmed organically by 2030.

However, some adverse impacts of agricultural production remain visible in the EU, most notably the continued and dramatic decline of common farmland birds. On a more positive note, the EU land area at risk of severe soil erosion by water has decreased slightly, as have the ammonia emissions from agriculture. Additionally, nitrate concentrations in EU groundwater bodies have shown a slight decreasing trend since 2015.

Available data for **SDG 6 'Clean water and sanitation'** paint a rather mixed picture for the EU. On the positive side, the share of people without appropriate sanitation facilities in their

households has been steadily decreasing in the EU, and connectivity to at least secondary waste water treatment has been improving slowly. However, trends regarding water quality are less favourable in the EU. While the biochemical oxygen demand in rivers and the nitrate concentrations in European groundwater bodies have decreased since 2015, phosphate concentrations in rivers have risen more or less continuously since 2013. Additionally, the share of inland bathing sites with excellent water quality has been falling in the EU Member States since 2017. Trends in water scarcity are also somewhat unfavourable, with the EU's water exploitation index showing a slightly increasing trend in recent years.

The goal-level assessment of **SDG 7 'Affordable and clean energy'** is influenced by two main factors. Firstly, energy consumption in the EU has increased in 2021 alongside the

economic recovery, after reaching a historic low in the pandemic year 2020. Secondly, the recent agreements between the Council and the Parliament on more ambitious energy targets for 2030 ⁽⁶⁾ mean that much stronger progress will be required in the coming years in the areas of energy efficiency and renewable energies than the one observed in the period assessed in this report (2016 to 2021). In 2021, both primary and final energy consumption increased from their 2020 low, even though consumption remained below pre-pandemic levels. Similarly, final energy consumption in households rose strongly in 2021.

The increased energy demand pushed down energy productivity and the share of renewables in 2021, even though the trends since 2016 remain positive in both areas. Additionally, the EU has been able to reduce its energy import dependency since 2019, especially for natural gas and solid fossil fuels. Furthermore, access to affordable energy has kept improving in the EU, with ever fewer people being unable to afford keeping their home adequately warm. However, it is important to note that the strong increase in energy prices observed in 2022 is not yet reflected in these data.

The overall assessment of progress towards **SDG 13 'Climate action'** is characterised by slightly more negative than positive trends in the selected indicators. While

according to provisional estimates for 2021, the EU has already reduced its net greenhouse gas emissions by about 30% since 1990 ⁽⁷⁾, stronger progress will be required to meet the ambitious 55% reduction target for 2030. Respective additional measures are already part of the Fit for 55 package. It is important to note that this assessment does not take into account further developments such as the pathways and planned measures outlined in the National Energy and Climate Plans (NECPs) of the Member States. Additionally, the carbon removals achieved by the land use and forestry sector (LULUCF) that contribute to the overall net GHG emissions have declined in recent years. Moreover, the share of renewable energy would need to rise much more strongly than it did during the period assessed (2016 to 2021) for the EU to meet its new, more ambitious 2030 target. While the average CO₂ emissions efficiency of new passenger cars had shown considerable improvement up to 2020, a methodological change in the testing procedure prevents comparison with the most recent data for 2021 ⁽⁸⁾. Concerning climate impacts and adaptation, the monetary losses from weather- and climate-related disasters rose sharply in 2021. On a positive note, the number of signatories to the Covenant of Mayors for Climate and Energy continues to grow, even though the trend stalled in 2022 compared with 2021. Moreover, the EU's contribution to climate finance for developing

countries has increased almost continuously over the past few years.

The indicators selected for **SDG 15 'Life on land'** show some slight improvements combined with a few clearly negative developments that result in an overall slightly negative goal-level assessment. While the EU's forest area has increased, pollutant concentrations in European rivers have shown mixed trends, with improvements in the biological oxygen demand occurring alongside increases in phosphate concentrations. Regarding land degradation, pressures from land take, including soil sealing by impervious materials, have continued to intensify, while the EU land area at risk of severe soil erosion by water has shrunk slightly since 2010. Even though terrestrial protected areas have increased across Member States since 2013, the EU continues to face dramatic long-term declines in common bird and grassland butterfly populations. The overall assessment of SDG 15 in this report thus confirms the results of other stocktaking reports and evaluations, which conclude that the conservation status of ecosystems and biodiversity in the EU is unfavourable, and that the negative impacts of EU life-style patterns on (global) biodiversity are considerable ⁽⁹⁾.

The overall assessment of EU developments regarding **SDG 17 'Partnerships for the goals'** is moderately negative. Favourable developments are only visible in two areas. EU

imports from developing countries grew strongly in 2021 and 2022 after the interruption to trade flows by the COVID-19 pandemic, and the share of households enjoying high-speed internet connections has increased sharply since 2018. Developments in the remaining indicators have been moderately or clearly unfavourable. Overall EU financing to developing countries has fallen strongly since 2016, and the EU's ratio of official development assistance (ODA) to gross national income (GNI) has not progressed towards the 0.7% target set for 2030. Concerning financial governance within the EU, even though the EU's overall debt-to-GDP ratio has fallen after reaching

a record high in 2020 as a consequence of the COVID-19 crisis and related public spending, it remained above pre-pandemic levels in 2022. Moreover, the already low share of environmental taxes in total tax revenues declined even further and reached a new low in 2021.

Summary of short-term impacts

Previous editions of the EU SDG monitoring report have shown that already before the COVID-19 crisis, progress towards the SDGs in the EU was uneven, with some areas requiring more attention and action. In the midst of the recovery from the pandemic, the EU was hit by the consequences of Russia's military aggression against Ukraine starting in early 2022. While the impacts of COVID-19 are now visible in most of the annual data used in the thematic chapters in this report, a dedicated section at the beginning of this report (see page 31) makes use of short-term (monthly and quarterly) data to show the more recent impacts of Russia's war of aggression through 2022 and early 2023.

The EU's response to the Russian invasion included humanitarian support by providing temporary protection to those fleeing Ukraine, financial support to Ukraine, and putting in place economic sanctions on the Russian government, companies and individuals. The majority of Europeans consider the EU's overall response to be satisfactory ⁽¹⁰⁾, even though the consequences of the Russian invasion are already clearly visible in the EU. Available short-term statistics show a considerable decline in Russia's share of EU energy imports alongside a reduction in the EU's overall demand for natural gas. Nevertheless, despite the EU's efforts to diversify its energy sources and reduce its dependence on Russia, the EU economy has seen a price hike for energy that has been influencing prices for housing and increasingly food products. As the Russian invasion continues even one year after it began, the long-term effects on the EU's economic and social fabric remain to be seen. With more data becoming available, future SDG monitoring reports might present a more detailed and nuanced picture on the consequences of Russia's military aggression against Ukraine.

Introduction

About this publication

Sustainable development objectives have been at the heart of European policy-making for a long time, firmly anchored in the European Treaties (1) and a mainstream part of key projects, sectorial policies and initiatives. The 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals (SDGs), adopted by the United Nations (UN) in September 2015, have given a new impetus to global efforts to achieve sustainable development. The EU and its Member States are committed to this historic global framework agreement and to playing an active role in maximising progress towards the SDGs.

The von der Leyen Commission has made sustainability an overriding political priority for its mandate. All SDGs feature in one or more of the six headline ambitions for Europe announced in the [Political Guidelines](#), making all Commission work streams, policies and strategies conducive to achieving the SDGs. Key elements of the Commission's 'whole of government' approach for delivering on the 2030 Agenda include the design of deeply transformative policies such as the ['European Green Deal'](#) and the integration of the SDGs into the European Semester. The European Green Deal aims to transform the Union into a modern, resource-efficient and competitive economy where climate and environmental challenges are addressed and turned into opportunities, while making the transition just and inclusive for all. The Commission's overall approach

to implementing the SDGs is described in the staff working document (SWD) ['Delivering on the UN's Sustainable Development Goals — A comprehensive approach'](#).

Eurostat supports this approach through regular monitoring and reporting on progress towards the SDGs in an EU context. This publication is the seventh edition of Eurostat's series of monitoring reports, which provide a quantitative assessment of the EU's progress towards reaching the SDGs. This publication is based on the [EU SDG indicator set](#), which includes indicators relevant to the EU and enables the monitoring of progress towards the goals in the context of long-term EU policies. It is aligned as far as appropriate with the UN list of global indicators, but it is not completely identical. This allows the EU SDG indicators to focus on monitoring EU policies and on phenomena particularly relevant in a European context.

The Eurostat monitoring report is a key tool for facilitating the coordination of SDG-related policies at both EU and Member State levels. As part of this process, it promotes the ongoing assessment and monitoring of progress on

implementing the SDGs, and helps to highlight their cross-cutting nature and the links between them.

This 2023 edition of the EU SDG monitoring report begins with a synopsis of the EU's overall progress towards the SDGs, followed by a presentation of the policy background at the global and EU levels and the way the SDGs are monitored at EU level (see the following pages in this chapter). The detailed monitoring results

are presented in 17 chapters, one for each of the 17 SDGs. This is preceded by an analysis of how the recent crises, such as the COVID-19 pandemic and Russia's invasion of Ukraine, have influenced the EU on its way towards achieving the SDGs, followed by an analysis of spillover effects. The report closes with a 'country overviews' chapter on status and progress of EU Member States towards the SDGs. The Annexes contain notes on methods and sources.

The 2030 Agenda for Sustainable Development

'Development which meets the needs of the current generations without compromising the ability of future generations to meet their own needs'. This is the definition of sustainable development that was first introduced in the [Brundtland report](#) by the World Commission on Environment and Development (WCED) in 1987, and it is the one most widely used nowadays. Following the Brundtland report were several important milestones in the international pursuit of sustainable development: the Rio Declaration on Environment and Development (1992), the World Summit for Social Development (1995), the Programme of Action of the International Conference on Population and Development (ICPD) (1994), the Beijing Platform for Action (1995), the Millennium Declaration (from which the Millennium Development Goals were derived), the World Summit on Sustainable Development (2002), the 2005 World Summit and the UN Conference on Sustainable Development (Rio+20) in 2012. Together, they paved the way for the [2030 Agenda](#).

In September 2015, the UN General Assembly (UNGA) adopted the '[Transforming our world: the 2030 Agenda for Sustainable Development](#)' document. The 2030 Agenda is the current global sustainable development agenda. At the core of the 2030 Agenda is a list of 17 SDGs (see Figure I.1) and 169 related targets to end poverty, protect the planet and ensure prosperity and peace. The Agenda also calls for a revitalised global partnership to ensure its implementation. The

SDGs are unprecedented in terms of significance and scope by setting a wide range of economic, social and environmental objectives and calling for action by all countries, regardless of their level of economic development. The Agenda emphasises that strategies for ending poverty and promoting sustainable development for all must go hand-in-hand with actions that address a wider range of social needs and which foster peaceful, just and inclusive societies, protect the environment and help tackle climate change. Although the SDGs are not legally binding, governments are expected to take ownership and establish national frameworks for achieving the 17 goals.

Monitoring of the SDGs takes place at various levels: global, regional, national, local and thematic. The UN High-Level Political Forum (HLPF) is the UN's central platform for following up and reviewing the 2030 Agenda and the SDGs at the global level. To this end, the 2030 Agenda encourages UN member states to conduct voluntary national reviews of progress towards the SDGs (?). Regular reviews by the HLPF are voluntary, state-led and undertaken by both developed and developing countries. In July 2023, the European Commission will present its first voluntary review, reflecting on the collective effort of the EU and its Member States regarding implementation of the SDGs. This will be the first time a voluntary review will be presented not by a country but by a supranational union, such as the EU.

In order to follow up and review the goals and targets, a set of global indicators was designed

Figure I.1: The UN Sustainable Development Goals

by an Inter-Agency and Expert Group (IAEG-SDGs) under the supervision of the UN Statistical Commission⁽³⁾. In July 2017, the UNGA adopted a [global SDG indicator list](#), including 232 indicators. A comprehensive review of the indicator framework in early 2020 resulted in the approval of 36 major changes to the global SDG indicator list, including additions and deletions. Therefore, the revised global indicator framework now consists of 231 indicators. Another such review is planned for 2025.

Every year, the UN releases a Report of the Secretary-General on 'Progress towards the Sustainable Development Goals', followed by an [SDG report](#) for the broader public. The latter provides an overview of progress on each of the 17 SDGs based on selected indicators from the global indicator framework.

The global indicator framework used to monitor the implementation of the 2030 Agenda is complemented by indicators at the level of UN world regions and at national level. For example,

indicator sets have been developed for the [Asia-Pacific region](#), for [Africa](#) and for [Latin America and the Caribbean](#). At the European level, the UN Economic Commission for Europe (UNECE) selected 80 indicators from the global list based on relevance for the region and data availability for a newly developed [UNECE SDG Dashboard](#). The UNECE also published a [first edition of a Roadmap on Statistics for Sustainable Development Goals](#) in July 2017 and a [second edition](#) in February 2022. The latest roadmap aims to provide guidance to members of national statistical systems and other stakeholders on how to best navigate the complex task of measuring the achievement of the 2030 Agenda's goals and targets. The roadmap covers different aspects such as national coordination, reporting on global SDG indicators, tracking progress at various levels, quality assurance, leave no one behind, communication, Voluntary National Reviews and capacity development. The EU SDG indicator set is in line with the UNECE roadmaps.

Sustainable development in the European Union

Sustainable development is not only a core principle for the European Union but also an overriding political priority for the von der Leyen Commission, which is reflected in the six headline ambitions for Europe announced in the [Political Guidelines](#) (see Figure I.2) and the investment priority areas of the Global Gateway strategy. Each Commissioner is responsible for ensuring that the policies under his or her oversight reflect the Sustainable Development Goals, while the college

of Commissioners is jointly responsible for implementing the 2030 Agenda. The President has set out a 'whole-of-government approach' towards implementing the SDGs (see Figure I.3).

Several major policy documents have shaped the EU's approach to implementing the SDGs. A communication from 2016 '[Next steps for a sustainable European future: European action for sustainability](#)' announced the integration of the SDGs into the European policy framework. As a

Figure I.2: The European Commission Priorities

Figure I.3: The Commission's 'Whole-of-Government approach' to implementing the Sustainable Development Goals

consequence, the EU has been monitoring the implementation of the SDGs since 2017 via annual SDG monitoring reports. In addition, a reflection paper '[Towards a Sustainable Europe by 2030](#)' from 2019 highlighted the complex challenges the EU is facing and identified the competitive advantages that implementing the SDGs would offer the EU. Since late 2019, the von der Leyen Commission has presented many transformative policies aimed at delivering on the many aspects of sustainability in the EU and beyond. The EU's approach to implementing the 2030 Agenda is briefly summarised below and described in detail in a staff working document (SWD) '[Delivering on the UN's Sustainable Development Goals — A comprehensive approach](#)'. For a complete overview of the European Commission's activities related to SDG implementation, see the [Commission's website on the EU's holistic approach to sustainable development](#).

The [European Green Deal](#), adopted in December 2019, is the EU's new growth strategy and aims to transform the Union into a climate neutral society while leaving no one behind (see Figure I.4). It aims to create a modern, resource-efficient, competitive and fair economy where there are no net emissions of greenhouse gases by 2050 and where economic growth is decoupled from resource use.

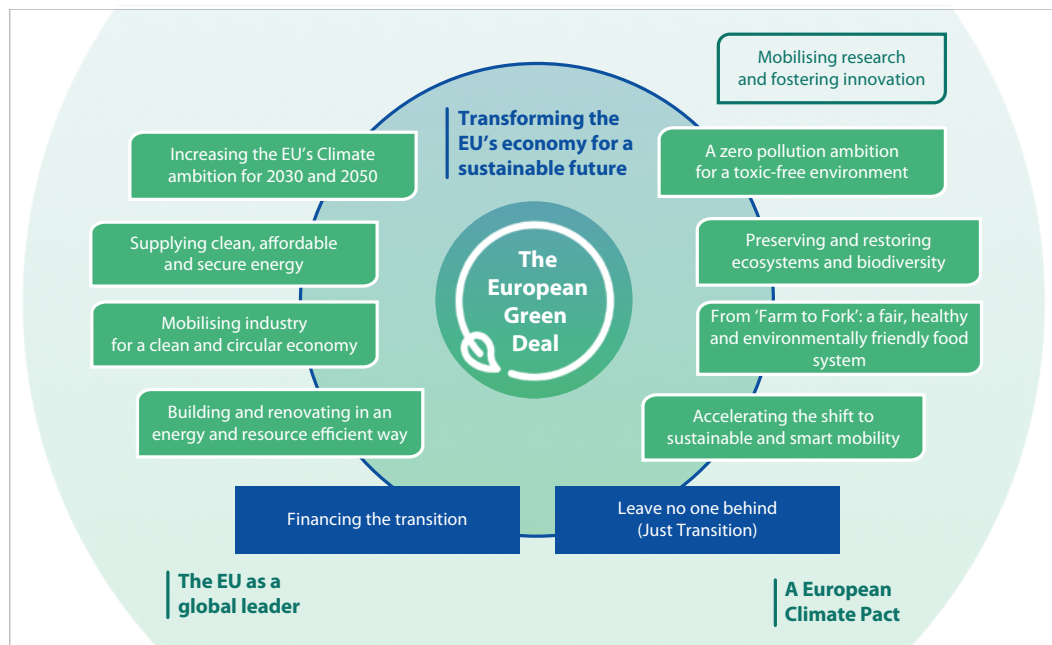

It also aims to protect, conserve and enhance the EU's natural capital and to protect the health and well-being of citizens from environment-related risks and impacts. It is also an integral part of the Commission's strategy to implement the 2030 Agenda and the SDGs.

In March 2020, a new [Circular Economy Action Plan](#) was adopted by the European Commission, introducing measures along the entire life cycle of products. The new Plan focuses on design and production for a circular economy, with the aim of ensuring that the resources used are kept in the EU economy for as long as possible.

The [EU Bioeconomy Strategy](#) provides a cross-cutting framework to enable transformative innovations with regards to the use of biological resources, and to ensure that the supply of biomass for food and bio-based products fully respects the finite planetary boundaries. A sustainable circular bioeconomy contributes to the European Green Deal objectives, by mitigating against climate change through renewable products and energy, substituting fossil fuels and other carbon-intensive materials, and contributing to carbon storage in products and ecosystems.

In May 2020, another important initiative that lies at the heart of the European Green Deal

Figure I.4: The European Green Deal

was adopted — the [Farm to Fork Strategy](#). The strategy aims to make food systems in the EU fair, healthy and environmentally friendly by ensuring sustainable food production, processing, distribution and consumption, and by minimising food loss.

The [EU Biodiversity strategy for 2030](#), also adopted in May 2020 as a part of the Green Deal, aims to put Europe's biodiversity on a path to recovery by 2030, and contains specific actions and commitments, such as establishing a large EU-wide network of protected areas on land and at sea, launching an EU nature-restoration plan and introducing measures to tackle the global biodiversity challenge.

The [2030 Climate Target Plan](#) from September 2020 envisions reductions in greenhouse gas emissions to at least 55 % below their 1990 level by 2030 and sets Europe on a responsible path to becoming climate-neutral by 2050. This ambition was legally enshrined in July 2021 with the adoption of the [European Climate Law](#). Under the heading of 'Delivering the European Green Deal', the Commission put forward several legislative

proposals, actions and targets for making Europe the first climate-neutral continent. These relate to the necessary transformation of our economies and societies, sustainable transport, clean energy, renovation of buildings, enhancing natural carbon sinks, and boosting global climate action. The [Council Recommendation on ensuring a fair transition towards climate neutrality](#) aims to ensure that the Union's transition towards a climate-neutral and environmentally sustainable economy by 2050 is fair and leaves nobody behind. It sets out specific guidance to help Member States devise and implement policy packages to address the employment and social aspects for promoting a fair transition across all policies, notably climate, energy and environmental policies, as well as for making optimal use of public and private funding.

The [Sustainable and Smart Mobility Strategy](#), adopted in December 2020, lays the foundation for how the EU transport system can achieve its green and digital transformation and become more resilient to future crises.

The [Chemicals Strategy for Sustainability](#) published in October 2020 is part of the EU's zero pollution

Figure I.5: Global Gateway and its key areas of partnership

ambition. The [Zero Pollution Action Plan](#) released in May 2021 calls for air, water and soil pollution to be reduced to levels no longer considered harmful to health and natural ecosystems, respecting the boundaries within which the planet can cope, thereby creating a toxic-free environment.

The [European Pillar of Social Rights Action Plan](#) outlines concrete actions to further implement the 20 principles of the European Pillar of Social Rights as a joint effort by the Member States and the EU, with the active involvement of social partners and civil society. The revised Social Scoreboard, which is also linked to the SDGs, was presented as part of the Action Plan to monitor progress towards the implementation of the Social Pillar principles within the European Semester. The Action Plan also proposes employment, skills and poverty reduction headline targets for the EU to achieve by 2030. The new 2030 headline targets are consistent with the UN Sustainable Development Goals and set the common ambition for a strong Social Europe.

Meanwhile, the 2021 update of the EU's new [Industrial Strategy](#) supports the twin transition to a green and digital economy. It seeks to ensure that the European industry leads the way in delivering

the EU's goals for a green, inclusive and resilient future. The strategy aims to boost support for the renewable energy and climate transition, while reinforcing the EU's strategic autonomy. In early 2023, the Commission moreover launched a [Green Deal Industrial Plan](#) to enhance the competitiveness of the EU's net-zero industry and support the transition to climate neutrality. The plan aims to provide a more supportive environment for scaling up the manufacturing capacity of the net-zero technologies and products that are required to meet the EU's climate targets. The Communication '[Long-term competitiveness of the EU: looking beyond 2030](#)' complements the Green Deal Industrial Plan with a long-term and comprehensive approach to the competitiveness of the EU.

Building on the European Green Deal, the [8th Environment Action Programme \(EAP\)](#), adopted in March 2022, anchors the Member States' commitment to environmental and climate action until 2030, guided by a long-term vision to 2050 of well-being for all, while staying within the Earth's planetary boundaries. The 8th EAP has six priority objectives related to climate neutrality, climate adaptation, circular economy, zero pollution, protecting and restoring biodiversity, and reducing

environmental and climate pressures related to production and consumption. In addition, the programme sets out an enabling framework and a monitoring framework to measure progress towards the required systemic change.

Over the past few years, the EU has adopted numerous other policies covering topics related to the SDGs. The [European Consensus on Development](#), adopted in 2017, defines the EU's shared vision and action framework for development cooperation. [Global Gateway](#) is the EU's strategy to support its partner countries in boosting smart, clean and secure links in digital, energy and transport sectors, and to strengthen health, education and research systems. Global Gateway is fully aligned with the 2030 Agenda and the SDGs as well as the Paris Agreement, and brings together the EU, its Member States and their financial and development institutions as Team Europe.

The Team Europe approach was initially launched in early 2020, as a [package](#) to support partner countries in the fight against the COVID-19 pandemic and its consequences, and to ensure a coordinated and comprehensive response between the EU and its Member States. The approach has quickly become the backbone of Global Europe (the main financial tool for EU international cooperation from 2021 to 2027) and its programming. It notably includes the conception of Team Europe Initiatives, which are the flagships of the Team Europe approach. The [European Democracy Action Plan](#) was adopted the same year to empower citizens and build more resilient democracies across the EU.

Furthermore, [EU cohesion policy](#), including the European Regional Development Fund (ERDF), the European Social Fund+ (ESF+), the Cohesion Fund and the Just Transition Fund (JTF), is also strongly aligned with the SDGs. It contributes to strengthening economic, social and territorial cohesion in the EU and correcting imbalances between countries and regions. It delivers on the Union's political priorities, especially the green and digital transitions.

The EU research and innovation programme [Horizon Europe](#) aims to support researchers and

innovators to drive the systemic changes needed to ensure a green, healthy and resilient Europe.

In line with the [Political Guidelines](#), the SDGs have also been progressively integrated into the [European Semester](#). This year, the SDG monitoring report is for the second time published at the same time as the Spring Package. Moreover, each European Semester country report includes an annex discussing the country's status, compared to the EU average, and progress in each SDG. The publication of the [Annual Sustainable Growth Survey \(ASGS\) 2023](#) in November 2022 launched the [2023 European Semester cycle](#). This ASGS outlines an economic policy agenda to mitigate the negative impacts of energy shocks in the short term and to keep up efforts to support sustainable and inclusive growth and increase resilience in the medium term, while maintaining flexibility to tackle new challenges.

The [national Recovery and Resilience Plans \(RRP\)](#) are structured around six thematic pillars to which they contribute, as mentioned in the Regulation on the [Recovery and Resilience Facility](#): green transition; digital transformation; economic cohesion, productivity and competitiveness; social and territorial cohesion; health, economic, social and institutional resilience; and policies for the next generation. In doing so, they also cover the four dimensions of competitive sustainability outlined in the 2023 ASGS: (1) environmental sustainability, (2) productivity, (3) fairness and (4) macroeconomic stability. Each of these dimensions relate to a set of SDGs and therefore the reforms and investments in the RRP's are also expected to contribute to progress towards them. In the context of Europe's climate ambitions and of the digital transformation, all RRP's need to focus strongly on both reforms and investments supporting the green and digital transitions. Each plan must commit a minimum of 37 % of the allocated funds to climate action and 20 % to digital spending. The plans approved have gone even beyond this and, on average, dedicate around 40 % of resources to climate-related measures and more than 26 % to the digital transition.

Monitoring sustainable development in the EU

The European Commission is committed to monitoring progress towards the SDGs in the EU context. Since the adoption of the first EU SDG indicator set in May 2017, Eurostat has led the further development of the indicator framework in close cooperation with other Commission services, the European Environment Agency and Member State organisations in the European Statistical System (ESS), involving also Council Committees and Working Parties as well as the civil society.

The EU SDG indicator set is structured along the 17 SDGs and covers the social, economic, environmental and institutional dimensions of sustainability as represented by the Agenda 2030. Each SDG is covered by five to six main indicators. They have been selected to reflect the SDGs' broad objectives and ambitions. Out of 100 indicators, 33 are 'multi-purpose', meaning they are used to monitor more than one goal. This allows the link between different goals to be highlighted and enhances the narrative of this monitoring report. Sixty-eight of the current EU SDG indicators are aligned with the UN SDG indicators.

The UN indicators are selected for global level reporting for countries at all levels of development and are therefore not always relevant in an EU context. The EU SDG indicators have been selected to take into account their policy relevance from an EU perspective, availability, country coverage, data freshness and quality. They have strong links with EU policy initiatives, which means that preference is given to indicators which are also part of a high-level scoreboard of EU policies such as the Social Scoreboard for the European Pillar of Social Rights Action Plan or the Monitoring Framework for the 8th EAP. The EU SDG indicator set is open to regular reviews to consider new policy developments and include new indicators as methodologies, technologies and data sources evolve over time. The reviews involve many Commission services, European agencies such as the European Environment Agency (EEA), Member State institutions in the ESS, Council Committees and Working Parties as well as the civil society.

Based on the most recent EU SDG indicator set, the SDG monitoring reports also provide an assessment of trends vis-à-vis SDG-related EU objectives and targets, visualised by arrow symbols. The assessment method considers

Table I.1: Explanation of symbols for indicating progress towards SD objectives and targets

Symbol	With quantitative target	Without quantitative target
	Trends for indicators marked with this 'target' symbol are calculated against an official and quantified EU policy target. In this case the arrow symbols should be interpreted according to the left-hand column below. Trends for all other indicators should be interpreted according to the right-hand column below.	
	Significant progress towards the EU target	Significant progress towards SD objectives
	Moderate progress towards the EU target	Moderate progress towards SD objectives
	[Category not applicable]	No progress towards SD objectives
	Insufficient progress towards the EU target	Moderate movement away from SD objectives
	Movement away from the EU target	Significant movement away from SD objectives
:	Calculation of trend not possible (for example, time series too short)	

Analysis of EU short-term progress towards the SDGs in the face of multiple crises

Sustainable development warrants a strong foundation supported by peace and security. However, 2022 was marred by multiple crises that affect the 2030 Agenda and the SDGs, threatening the achievement of the global goals. More than a year after the beginning of the Russian war of aggression against Ukraine, the consequent ripples of social and economic disruptions are still felt throughout the world. The ongoing humanitarian crisis in Ukraine has led to a mass displacement of people now seeking refuge in the EU and other neighbouring countries, thereby directly impacting several SDGs. The war is perceived as a fundamental change in the lives of people, with 61 % of Europeans being confident that their life will not continue unchanged ⁽¹⁾. Further, the complex economic ties with Russia and their disruption as a result of war and sanctions have reverberations across the EU and beyond. Sharp rises in food and energy prices, combined with other impacts of the Russian invasion, hinder the implementation of the 2030 Agenda. These impacts further exacerbate the ongoing crises of climate change and environmental destruction and make achieving the SDGs even more challenging.

The analysis in this chapter is done in the context of SDG monitoring, using breakdowns of the EU SDG indicators and other short-term indicators, such as quarterly greenhouse gas emissions, for illustrating some short-term effects on the EU's progress towards the SDGs in the face of multiple crises, with a focus on the war in Ukraine. Many effects of the COVID-19 pandemic are discussed in the thematic SDG chapters of this report (see, for example, the chapters on SDG 3, SDG 7 and SDG 8).

While the EU economy has recovered after the COVID-19 pandemic, inflationary pressures have risen

The Russian invasion of Ukraine in February 2022 hit Europe at a time when it was just recovering from the economic disruptions caused by the COVID-19 pandemic. Previously, following the lockdown measures put in place by EU Member States to halt the spread of COVID-19, the EU's economy (SDG 8) experienced a considerable drop in real gross domestic product (GDP) per capita, by 5.7 % in 2020 compared with 2019. However, by 2021, many economic indicators had bounced back to almost pre-pandemic levels. Starting from the second quarter of 2021, GDP in the EU has increased continuously, resulting in an annual growth of real GDP per capita by 3.3 % in 2022 compared with 2021 ⁽²⁾.

While overall industrial production (in value added terms) (SDG 12) had fallen significantly in 2020 owing to the pandemic, it has since made a significant recovery and in 2022 exceeded pre-pandemic levels, leading to an annual increase of 3.0 % in 2022 compared with the previous year ⁽³⁾. However, this trend was largely driven by the manufacturing sector. In contrast, production (in value added terms) in electricity, gas, steam and air conditioning supply fell by 1.8 % in the first quarter of 2022 compared with the last quarter of 2021 and has since been gradually declining (see Figure II.1). In the fourth quarter of 2022, the production volume of this sector was around 11 % lower than in the last quarter of 2021 ⁽⁴⁾.

Figure II.1: Production in industry, EU, 2019–2022
(volume index of production, 2015 = 100)

Source: Eurostat (online data code: sts_inpr_q)

One of the most significant impacts of the recent crises is the rise in the EU's inflation rate since the start of 2021, reaching a peak of 11.5 % in October 2022 and affecting most goods and services. This increase in prices since 2021 can be attributed to a fast reopening of the economy after the pandemic and higher energy prices owing to lower oil and gas reserves from the previous year ⁽⁵⁾. The first quarter of 2022, which marked the beginning of Russia's military aggression towards Ukraine, exacerbated the price rise, particularly for

electricity, gas, solid fuels and heat energy (SDG 7). The inflation rate continued to increase for all categories throughout 2022, peaking in October 2022, which marked the height of the energy crisis in the EU. In that month, consumer prices for electricity and gas were 52.6 % higher than in October 2021. However, this rate has fallen from October 2022 through March 2023, with values lower than at the start of 2022, but still significantly higher than pre-pandemic levels ⁽⁶⁾.

Figure II.2: Inflation rate (HICP), EU, 2019–2023
(annual rate of change in %)

Source: Eurostat (online data code: prc_hicp_manr)

Figure II.3: Gross household saving rate, EU, 2019–2022

Source: Eurostat (online data code: [nasq_10_ki](#))

The inflation rate for the category of food and non-alcoholic beverages (SDG 2) has also been on the rise since 2021. However, unlike energy inflation, food price inflation has not shown a decline in recent months and continued to rise as of March 2023. Housing costs (SDG 1) followed the overall trend, showing an increase in 2021 and through most of 2022, with a decline towards the end of 2022 ⁽⁷⁾.

The economic disruptions brought about by the pandemic and Russia's invasion of Ukraine, which led to high energy prices and subsequent rise in the prices of goods and services, are also reflected in the evolution of the EU's gross household saving rate (see Figure II.3) (SDG 1). While the savings rate had remained stable at around 12.5 % in the year before the pandemic, it rose dramatically in the second quarter of 2020, reaching almost 25 %. Since 2021, however, the rate has shown a substantial decline, in parallel to the increase in the inflation rate described above. By the third and fourth quarters of 2022, the gross household saving rate had fallen back to the levels observed in 2019, at 12.0% and 12.6%, respectively ⁽⁸⁾.

The impact of rising prices on the standard of living are being felt by the public. According to the spring 2022 [Eurobarometer survey](#), carried out by the European Parliament around the start of the Russian invasion, almost nine in ten Europeans have either already experienced a reduction in their standard of living (SDG 1) which they expect

to continue (40 %), or expect such an impact to occur over the next year (47 %). Vulnerable socio-demographic groups in Europe were hit harder by the consequences of the invasion, including the elderly, citizens with lower formal education, those without employment, single parents, and those that otherwise have difficulties in making ends meet. In total, a majority of Europeans said they are not ready to face surging energy (58%) or food prices (59%). However, a similar majority of the Europeans surveyed (59%) considered the defence of common European values such as freedom and democracy (SDG 16) to be more important than maintaining prices and the cost of living.

The EU's energy import dependency on Russia has fallen

Russia's invasion of Ukraine and the consequent sanctions have impacted the international trade in goods, both directly and indirectly, especially causing disruptions in the trade of oil, natural gas and coal (SDG 7). In 2021, the year before the invasion, more than half of the EU's energy demand was met by imports, with the import dependency being particularly high for oil and petroleum products (91.7 %) and natural gas (83.4 %) ⁽⁹⁾. For both energy carriers, Russia was the most important supplier in 2021, accounting for 28.4 % of extra-EU imports of oil and petroleum products and for 44.1 % of extra-EU imports of natural gas ⁽¹⁰⁾. Starting from the first and second quarters of 2022, however, the share of energy

Figure II.4: EU imports of energy products, by partner, 2019–2022
(% of extra-EU imports)

Source: Eurostat (online data code: [ext_st_eu27_2020stic](#))

imports from Russia dropped significantly and continued to decline for the rest of the year. Between the first and the fourth quarters of 2022, the share of energy imports from Russia decreased from 25.8 % to 13.3 %. This relative reduction in dependence on Russia was substituted with increased imports from the United States, Norway and the United Kingdom, accounting for 12.6 %, 8.1 % and 6.1 % of the total energy imports in the fourth quarter of 2022, respectively ⁽¹⁾.

The gradual shift in trade partners away from Russia resulted in strong declines in the monetary value of Russia's share in extra-EU imports of natural gas, falling from 36 % in 2021 to 21 % in 2022 ⁽¹²⁾. The invasion also impacted EU's gas consumption, reducing it by 19.3 % in the period August 2022 to January 2023, compared with the average consumption for the same months between 2017 and 2022 ⁽¹³⁾.

At the start of 2022, Russia was also the largest supplier of crude oil to the EU, accounting for 31 % of imports, followed by the United States. The instability that came along with the Russian invasion was also reflected in the imports of crude oil from Russia, which first showed considerable fluctuations between February and April of

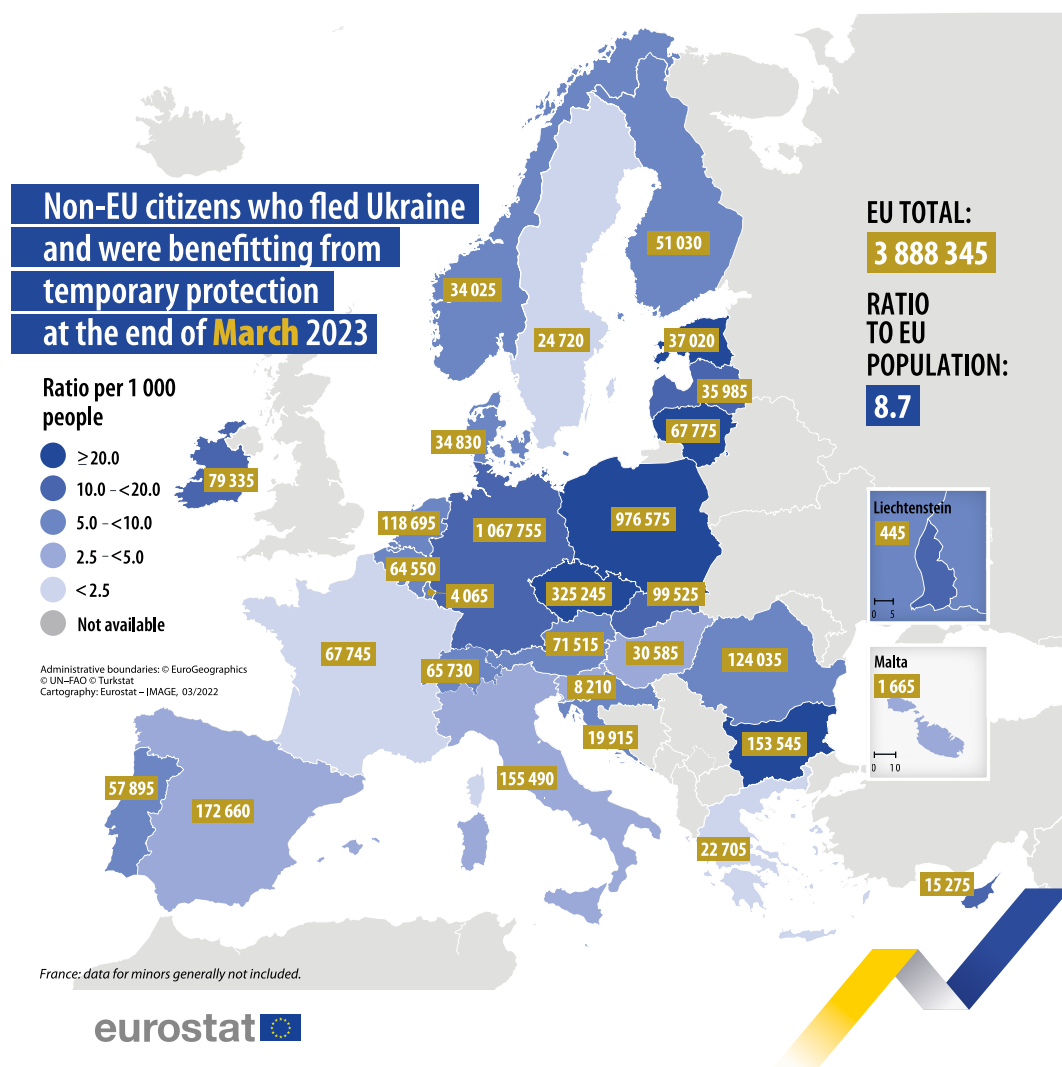

2022, followed by a significant decline from May 2022 onwards. In December 2022, crude oil imports from Russia were down to only 4 % of the total. This decline in imports from Russia was substituted with imports from the United States and Norway, amounting to 18 % and 17 % of the total imports of crude oil, respectively ⁽¹⁴⁾.

Temporary protection has been granted in the EU to those displaced by the Russian invasion of Ukraine

In addition to its effects on the economy and trade in energy, the Russian military aggression against Ukraine has left in its wake an influx of displaced people from the invasion (SDG 10) who have sought refuge in the EU and other neighbouring countries. Following the displacement caused, the [Council Decision of March 2022](#) enabled non-EU citizens fleeing Ukraine to receive immediate and temporary protection. The Decision originally granted temporary protection for one year but this has now been extended until March 2024, with provisions made for further extension conditional on how the situation evolves ⁽¹⁵⁾.

Map II.1: Non-EU citizens who fled Ukraine and benefitted from temporary protection at the end of March 2023

(total number and number per 1 000 inhabitants)

Source: Eurostat (online data codes: migr_asytpsm and demo_gind)

At the end of March 2023, about 3.9 million displaced people from Ukraine were beneficiaries of this temporary protection in the EU. Germany, Poland and Czechia hosted the highest absolute number of beneficiaries, providing temporary protection for around 61 % of all beneficiaries in the EU. Czechia, Estonia, Poland, Lithuania and Bulgaria provided the highest temporary protections relative to their populations. After the first half of 2022, the number of temporary protections sought decreased considerably, with the number of people granted temporary protection in the EU falling by about 65 % between the first and the last quarter of 2022. As of March 2023, a large proportion of temporary protection seekers were adult women (mainly aged 35 to 64 years), representing around 47 % of the total beneficiaries. The second largest group were children, amounting to about 35 % of the beneficiaries. Of the countries for which data is available, Belgium and Lithuania granted the most temporary protections to unaccompanied minors in the EU ⁽¹⁶⁾.

Greenhouse gas emissions have declined since the start of 2022

The more recent crises mentioned above also interfere with the EU's ambition of tackling the climate crisis. The COVID-19 pandemic and the related lockdown measures resulted in a short-term improvement in some indicators that are used as proxies to monitor climate change mitigation, such as energy use and greenhouse gas (GHG) emissions (SDG 7 and SDG 13). At the same time, there is evidence that the pandemic has caused harm to the environment (SDG 12 and SDG 15) in the form of increased pollution from single-use plastics (such as masks, gloves and take-away food containers) ⁽¹⁷⁾.

Given the revival of the economy after the COVID-19 pandemic, the EU's greenhouse gas (GHG) emissions increased by 2 % in the third quarter of 2022 compared with the same quarter of the previous year. However, relative to the pre-pandemic levels, GHG emissions remained 4 % below the level reported in the third quarter

Figure II.5: Quarterly greenhouse gas emissions, by economic activity, EU, 2015–2022
(million tonnes of CO₂-equivalent)

Note: Estimated data.

Source: Eurostat (online data code: [env_ac_aigg_q](#))

of 2019. The highest increases in GHG emissions between the third quarters of 2021 and 2022 were observed in transportation and storage (9%), electricity and gas supply (5%), and services excluding transport and storage (4%). Over the same period, GHG emissions from agriculture, manufacturing and water supply declined slightly by around 1% or less. The EU's overall GHG emissions have declined since the start of 2022, indicating that despite the economic rebound, the EU managed to continue the long-term downward trend of GHG emissions trend ⁽¹⁸⁾.

Conclusions

The EU had already strayed off its path to achieving the 2030 Agenda and the SDGs as a result of the pandemic sweeping the world. Russia's military aggression against Ukraine and the consequent social and economic disruptions, in addition to the substantial loss of life and property, have been felt throughout the EU and other parts of the world. The invasion also highlighted the energy dependency of the EU, and other parts of the world, on Russia and impacted EU citizens directly through rising living costs. Combined with the ongoing climate crisis, these short-term crises have created significant hurdles for attaining the SDGs.

The EU's response has included humanitarian support by providing temporary protection

to people fleeing Ukraine, financial support to Ukraine and placing economic sanctions on the Russian government, companies and individuals. The majority of Europeans consider the EU's overall response to be satisfactory ⁽¹⁹⁾, even though the consequences of the Russian invasion are already clearly visible in the EU. Despite the EU's efforts to diversify its energy sources and reduce its dependence on Russia, the EU economy has seen a price hike for energy that has influenced prices for housing and increasingly food products. Conversely, the household saving rate has fallen back to pre-pandemic levels, after peaking during the COVID-19 crisis. In the area of energy, available short-term statistics show a considerable decline in Russia's share of EU energy imports alongside a reduction in the EU's overall demand for natural gas. These developments might also help the EU to meet its long-term climate targets. While the available short-term data for 2022 suggest a slight increase in GHG emissions compared with 2021, EU emissions remain below pre-pandemic levels and appear to continue their long-term downward trend.

One year on from the onset of Russia's invasion, the long-term effects on the EU's economic and social fabric remain to be seen. With more data becoming available, future SDG monitoring reports might present a more detailed and nuanced picture of the consequences of Russia's military aggression against Ukraine.

1

End poverty in all its forms everywhere

SDG 1 calls for the eradication of poverty in all its manifestations. It envisions shared prosperity, a basic standard of living and social protection benefits for people everywhere, including the poorest and most vulnerable.

Poverty harms people's lives and hampers social cohesion and economic growth. Monitoring SDG 1 in an EU context involves tracking aspects related to multidimensional poverty and basic needs. Over the assessed five-year period, the EU has made quite strong progress in all aspects of poverty monitored here. The share of the population affected by different forms of poverty, such as monetary poverty or material and social deprivation, has decreased. However, while the number of people at risk of poverty or social exclusion has fallen, stronger progress will be necessary to meet the 2030 target to lift at least 15 million people out of poverty or social exclusion, along with the complementary ambition that at least 5 million of these should be children. With regard to basic needs, significant progress has been made for all indicators, with fewer people now overburdened by housing costs, reporting an unmet need for medical care or living in an overcrowded household.

Table 1.1: Indicators measuring progress towards SDG 1, EU

Indicator	Period	Annual growth rate	Trend	Where to find out more
Multidimensional poverty				
 People at risk of poverty or social exclusion	Time series too short for long-term assessment		:	page 47

Note: See Annex I for a description of the methodology used for the growth rate calculation and the trend assessment. For indicators without a target, the growth rates observed over the specified periods are given. For indicators with a quantified EU target, both the observed growth rates and the growth rates that would have been required in the specified periods for meeting the target are given.

(*) Multi-purpose indicator.

Policy context

Multidimensional poverty

The [European Pillar of Social Rights \(EPSR\)](#) promotes upward convergence towards better living and working conditions in Europe. The [EPSR Action Plan](#) set a target to reduce the number of people at risk of poverty or social exclusion by 15 million by 2030, with the complementary ambition that at least 5 million should be children.

The [reinforced Youth Guarantee](#) strengthens prevention and activation of young people from vulnerable groups and will help reduce their poverty or social exclusion.

The European [Child Guarantee](#) helps to ensure that in Europe every child in need has effective and free access to quality early childhood education and care, education, school meals, healthcare, adequate housing and healthy nutrition.

The [Directive on adequate minimum wages](#) in the European Union from 2022 aims to improve living and working conditions, including through addressing in-work poverty.

The [Council Recommendation on minimum income ensuring active inclusion](#) from 2023 aims to combat poverty and social exclusion, and to pursue high levels of employment by promoting adequate income support, including by means of minimum income.

The [Council Recommendation on ensuring a fair transition towards climate neutrality](#) from 2022 provides policy guidance for addressing relevant employment and social aspects in the context of the green transition.

The [Commission Communication on better assessing the distributional impact of Member States' policies](#) calls for Member States to make the impact of planned measures and investments on the income of various groups more transparent.

The [Strategy for the Rights of Persons with Disabilities 2021–2030](#) aims to reduce the risk of poverty for persons with disabilities through measures, for example in the field of employment, health, accessibility or education.

The [European Social Fund Plus \(ESF+\)](#) is a key financial instrument for implementing the European Pillar of Social Rights. It supports the most deprived people and marginalised communities, addresses child poverty and supports the social integration of people at risk of poverty.

Basic needs

The [Fund for European Aid to the Most Deprived](#) supports EU countries' initiatives to provide food, clothing and other essential goods as well as non-material social inclusion measures, to the poorest in society. In 2020, amendments to the fund's Regulation introduced specific measures for addressing the COVID-19 crisis.

The [affordable housing initiative](#) is part of the Commission's [renovation wave](#) strategy for Europe, which aims to promote greener buildings, create jobs and improve lives. The initiative should ensure that social and affordable housing facilities also benefit from the renovation wave.

No poverty in the EU: overview and key trends

Multidimensional poverty

SDG 1 does not only call for the eradication of extreme poverty but also for poverty in all its dimensions to be halved by 2030. This global goal has a universal approach to reducing poverty. The EU also employs a multidimensional measure of poverty and in its [European Pillar of Social Rights Action Plan](#) has set a target to reduce the number of people at risk of poverty or social exclusion by at least 15 million by 2030 compared with the situation in 2019. A complementary ambition states that of these 15 million people, at least 5 million should be children.

The EU's [at-risk-of-poverty-or-social-exclusion \(AROPE\)](#) indicator is based on three components: monetary poverty; severe material and social deprivation; and very low work intensity. Through this multidimensional approach, the indicator shows which share of the population is at risk of exclusion and marginalisation from economic and social activities (¹).

Stronger progress is necessary to meet the 2030 target to reduce the number of people at risk of poverty or social exclusion

In 2021, 95.4 million people, equalling 21.7 % of the EU population, were [at risk of poverty or social exclusion](#). This represents a 7.9 % decrease since 2016, when 103.6 million people (or 23.7 % of the population) had been at risk. Nevertheless, the rate would need to fall more strongly in the next few years in order for the EU to meet its target of lifting at least 15 million people out of poverty or social exclusion by 2030. It is worth noting that the trends for many poverty-related indicators are affected by methodological changes

95.4
million people
in the EU
were at risk
of poverty or
social exclusion
in 2021

in the data collection from 2020 onwards in a number of Member States, in particular Germany and France (²).

The number of children aged less than 18 who were at risk of poverty or social exclusion amounted to 19.6 million in 2021, corresponding to 24.4 % of the population of this age group. This is an 11.3 % decrease compared with five years earlier, when 22.1 million children (27.1 %) were at risk of poverty or social exclusion across the EU. However, in order to meet the complementary ambition of lifting at least 5 million children out of this situation by 2030, the pace of this development would need to speed up over the next years.

Monetary poverty is the main form of poverty or social exclusion in the EU

[Monetary poverty](#) was the most prevalent component of poverty or social exclusion in the EU in 2021, affecting 73.7 million people or 16.8 % of the population. This means that after

[social transfers](#) (excluding pensions) these people had an [equivalised disposable income](#) of less than 60 % of the national median equivalised disposable income. The equivalised disposable income is the total income of a household — after tax and other deductions — that is available for spending or saving, divided by a specific scale which takes into account a household's composition and size. [Very low work](#)

[intensity](#), referring to people living in (quasi-)jobless households where the adults worked equal to or less than 20 % of their total work-time potential during the past year, affected 29.3 million people (equalling 8.9 % of the population) aged less than 65 years in 2021. In the same year, 27.1 million people (6.3 % of the EU population) were affected by severe material

73.7
million people
in the EU
were at risk
of monetary
poverty in 2021

and social deprivation, which meant they were unable to afford seven or more items out of a list of 13 elements of material goods, services or social activities considered by most people to be desirable or necessary for an adequate life (see page 50 for the full list).

The three components of the at-risk-of-poverty-or-social-exclusion indicator — monetary poverty, very low work intensity, and severe material and social deprivation — are related but distinct concepts that can overlap. This means that some people might be affected by two or even all three dimensions at the same time. According to its definition, *monetary poverty* is a relative measure and strongly depends on the median income level in a given country. This means that even during times of increasing median income, the relative poverty rate may remain stable or even increase, depending on changes in income distribution across the population. Rates of people living in households with *very low work intensity* (jobless or quasi-jobless households) and *severe material and social deprivation* (indicating a lack of resources to cover certain material and social needs) are likely to decrease during economic recoveries when people are generally better off financially and the labour market situation has improved. Of all of the 95.4 million people at risk of poverty or social exclusion in the EU in 2021, 28.7 million (30.1 %) were affected by more than one dimension of poverty, and 5.9 million (6.2 %) were affected by all three forms ⁽³⁾.

and social
deprivation in
2021

To reduce poverty, governments provide a wide range of measures, such as income support through various benefits (for example, unemployment benefits, sickness and invalidity benefits, and minimum income benefits), tax policies and provision of enabling, social and employment services. The impact of the transfers can be assessed by comparing the at-risk-of-poverty rate before and after social transfers, excluding pensions. In the EU, social transfers (excluding pensions) reduced the share of people at risk of monetary poverty in 2021 from 26.7 % ⁽⁴⁾ to 16.8 %, which corresponds to a reduction by 37.1 % ⁽⁵⁾.

Considerable differences in poverty rates exist within the EU

The multidimensional risk-of-poverty-or-social-exclusion rate differs considerably between Member States. In 2021, national rates for this indicator ranged from 10.7 % in Czechia to 34.5 % in Romania in 2021. While Czechia ranked among the best performing countries for all three components, other countries show striking differences in their situation in terms of monetary poverty, severe material and social deprivation, and very low work intensity, illustrating that good performance on one indicator does not necessarily go hand in hand with a similar performance on another. Romania, for example, had the second highest share of monetary poverty after social transfers and the highest share of severely materially and socially deprived people in 2021, while at the same time its share of (quasi-)jobless households was the lowest across the EU. Hungary is another example with striking differences with regard to the three components. It was among the best third of countries for monetary poverty after social transfers and share of (quasi-)jobless households, but had the fourth highest rate of severe material and social deprivation. These examples show that the drivers behind the Member States' at-risk-of-poverty-or-social-exclusion rates can vary, depending on the national context.

Children and young people are particularly affected by poverty and social exclusion

Children and young people are generally more affected by the risk of poverty or social exclusion than other age groups. People aged 20 to 24 were most likely to be at risk in 2021, with 27.6 % of this age group living in households that were at risk of poverty or social exclusion. This figure is 5.9 percentage points higher than the rate for the total EU population (21.7 %). Children aged 0 to 17 were also more affected than the overall EU population, with 24.4 % living in households at risk of poverty or social exclusion. In line with the overall EU trend, the poverty or social exclusion rates for both groups have decreased since 2016 ⁽⁶⁾.

Children aged 0 to 17 show a similar pattern for the three poverty dimensions as the total population, with monetary poverty being the most prevalent form, followed by quasi-joblessness and material and social deprivation. In 2021, 19.5 % of children aged 0 to 17 were living in households affected by monetary poverty after social transfers, 8.3 % were living in (quasi-)jobless households, and 7.5 % were living in households affected by severe material and social deprivation ⁽⁷⁾.

Children's risk of poverty or social exclusion is largely determined by the situation of their parents. Two major factors are education and household composition: parents with a lower level of education usually earn less. In 2021, 62.5 % of children aged 0 to 17 whose parents had at most lower secondary education were at risk of poverty or social exclusion. Very young children aged 0 to 5 were the most affected, with a rate of 67.0 %. Children with more highly educated parents fared significantly better. 28.5 % of children aged 0 to 17 and 29.8 % of children aged 0 to 5 whose parents had a mid-level education were at risk of poverty or social exclusion. The rates were 9.8 % for children aged 0 to 17 and 10.1 % for children aged 0 to 5 with highly educated parents ⁽⁸⁾. Similarly, households of (mostly female) single parents with one or more dependent children had a much higher at-risk rate (44.1 % in 2021) than any other household type ⁽⁹⁾.

Poverty is more likely to affect people who are unemployed or have a migrant background, a low level of education or a disability

Identifying situations that can make people more vulnerable to being at risk of poverty and social exclusion is important for designing sound policies that prevent and fight poverty. Figure 1.4 shows which subgroups of people were most at risk of poverty or social exclusion in 2021. In addition to the case of children and young people discussed previously, other characteristics — such as unemployment, a migrant background, low education levels or disabilities — were also key risk factors. Not surprisingly, the group with the highest at-risk-of-poverty-or-social-exclusion rate were unemployed people, of which two-thirds (64.5 %) were in this situation. Nearly half (48.4 %) of non-EU citizens living in the EU were at risk of poverty and social exclusion, far more than EU home-country nationals (19.5 %). The situation was similar when looking at country of birth, with 41.0 % of adults born in non-EU countries being in that situation, compared with only 19.0 % of those born in the reporting EU countries. Moreover, more than one-third of people with severe disabilities (36.2 %) or low education levels (34.7 %) were at risk of poverty or social exclusion. People living in rural areas (22.5 %) were slightly more affected than those in urban areas (21.9 %). Women (22.6 %) were more affected than men (20.7 %) ⁽¹⁰⁾.

The poverty gap has widened in the past decade, but the situation has improved in recent years

The poverty gap measures the 'depth' of poverty and is defined as the distance between the median income of people at risk of poverty and the **poverty threshold** (set at 60 % of the national **median** equivalised disposable income after **social**

transfers). In 2021, this gap amounted to 24.4 % in the EU, which means the median income of those below this poverty threshold was 24.4 % lower than the threshold itself. While this represents a 1.0 percentage point improvement compared with 2016, it is 1.3 percentage points above the level recorded in 2010, when the poverty gap amounted to 23.1 %.

In-work poverty has increased in the past ten years, with a peak in 2016

Having a paid job does not necessarily prevent people from being at risk of poverty. The share of people at risk of monetary poverty among the employed, the so-called **working poor**, has grown slightly since 2010. In 2021, the in-work poverty rate was 8.9 %, which is an increase of 0.4 percentage points compared with 8.5 % in 2010. However, in 2016 the rate had reached a peak of 9.8 %, so the 2021 figure represents a 0.9 percentage point improvement in the in-work poverty rate over the final five years of this period. Rates varied considerably across the EU in 2021, with the lowest share of in-work-poverty recorded in Finland (2.8 %) and the highest in Romania (15.6 %) and Luxembourg (13.5 %).

The likelihood of a person becoming a member of the 'working poor' varies according to their type of contract and education level. Low-skilled workers and people who work part-time or on temporary contracts are generally the most affected ⁽¹⁾.

Basic needs

Being at risk of poverty can have a severe impact on a person's ability to meet their basic needs such as being able to afford adequate housing or receive necessary medical treatment.

8.9 %
of employed
people in the
EU were at risk
of monetary
poverty in 2021

Fewer people are overburdened by their housing costs or face severe housing deprivation

The European Commission has declared access to affordable accommodation to be a fundamental need and right ⁽¹²⁾. Meeting basic human needs is central to social sustainability and housing is a key dimension of need. Housing costs often account for the largest component of many households' expenditure and determine what is left of their budget for satisfying other essential needs, such as education, medical treatment, food or energy. People suffering from poverty are far more often restricted to sub-optimal housing than the overall population.

Housing affordability can be analysed through the housing cost overburden rate, which is defined as the share of the population living in households where the total housing costs (net of housing allowances) represent more than 40 % of the total disposable household income. The EU's housing cost overburden rate has been on a downward path since 2010, when 10.0 % of the population were affected, falling to 8.3 % in 2021. Low-income households are particularly prone to being overburdened by their housing costs. In 2021, 33.0 % of people with an income below the poverty threshold spent 40 % or more of their household disposable income on housing, compared with only 3.4 % of the not at-risk-of-poverty population (referring to people with an income above the poverty threshold) ⁽¹³⁾. Similarly, people with disabilities are more likely to be overburdened by housing costs. Data are only

8.3 %
of the EU
population were
overburdened
by their housing
costs in 2021

4.3 %

population
faced severe
housing
deprivation in
2020

available for people aged 16 or over and show that in 2021, 9.1 % of people with severe and 8.7 % of people with some disability (activity limitation) were in this situation, compared with 6.9 % of people with no disability (activity limitation) ⁽¹⁴⁾.

The severe housing deprivation rate is an indicator of inadequate housing, referring to people living in an **overcrowded** household ⁽¹⁵⁾ that also meet the criteria for housing deprivation, defined by poor amenities such as a leaking roof, lack of sanitation facilities (bath, shower, indoor flushing toilet) or a dwelling that is too dark. In 2020, 4.3 % of the EU population faced severe housing deprivation, which is a 1.0 percentage point improvement compared with 2015. Among people living in monetary poverty, 10.2 % were affected by this situation in 2020, compared with only 3.2 % of the richer population ⁽¹⁶⁾.

An analysis by degree of urbanisation reveals that city dwellers in particular are more likely to be overburdened by their housing costs. In 2020, 9.9 % of people living in cities spent 40 % or more of their household disposable income on housing, compared with only 7.0 % for towns and suburbs and 5.8 % for rural areas. Severe housing deprivation was slightly more common in rural areas with 4.9 % than in cities with 4.8 % in 2020; in towns and suburbs the rate was 3.4 % in that year ⁽¹⁷⁾.

People who self-report unmet needs for medical care most commonly cite costs as the reason

Access to health care services is important for ensuring a high quality of life. In turn, this may contribute to increased productivity and reduced costs associated with social protection systems. Barriers to accessing health services include costs, distance and waiting time. In 2021, 2.0 % of the EU population aged 16 and above reported an unmet need for medical care. While the situation has improved by 0.8 percentage points compared with 2016, the rate has increased in the last four years. Cost was the main reason given for limited access to health care services, indicated by 1.0 % of the EU population in 2021. People with lower incomes face a much higher share of unmet need for medical care. While only 0.2 % of the richest 20 % of the population reported unmet care needs due to financial constraints, 2.2 % of people in the poorest quintile reported that this was the case ⁽¹⁸⁾.

End hunger, achieve food security and improved nutrition and promote sustainable agriculture

SDG 2 seeks to end hunger and malnutrition and ensure access to safe, nutritious and sufficient food. Realising this goal will largely depend on promoting sustainable production systems and increasing investment in rural infrastructure and agricultural research and development.

Achieving healthy diets and ensuring agricultural systems remain productive and sustainable are essential for achieving a healthy food system that is good for people and the planet. Monitoring SDG 2 in an EU context includes tracking developments in obesity, sustainability of agricultural production, and environmental impacts of agricultural activities on land, water and atmosphere. Over the past five years, progress towards SDG 2 has been modest. There have been strong improvements in labour productivity and public investments in farming, while modest progress has been seen on reducing some environmental impacts. However, growing obesity rates are harming health and well-being, and adversely affecting health and social systems, governmental budgets, and economic productivity and growth. At the same time, European ecosystems and the biodiversity within them continue to lose ground to intensive agriculture.

Policy context

Malnutrition

The [EU Action Plan on Childhood Obesity 2014–2020](#) aimed to help halt the rise in childhood obesity by 2020 by promoting healthy diets. The Commission will evaluate the 2014–2020 EU Action Plan on Childhood Obesity and propose a follow-up.

[Europe's Beating Cancer Plan](#) also highlights the importance of addressing obesity and diabetes from an early age.

Sustainable agricultural production

The [EU's Common Agricultural Policy \(CAP\)](#) provides income support, market measures and rural development measures to safeguard farmers' income and increase agricultural productivity while protecting rural landscapes and the environment.

The [EU Farm to Fork Strategy for sustainable food](#) aims to significantly reduce pesticide use, nutrient losses and the use of antibiotics. The strategy sets the 2030 targets of achieving a 25 % share of the EU's total farmland for organic farming and a significant increase in organic aquaculture, a 50 % reduction in the use and risk of chemical pesticides, a 50 % reduction in the use of more hazardous pesticides and a 50 % reduction in nutrient losses.

[Biodiversity Strategy for 2030](#) aims to bring back at least 10 % of agricultural area under high-diversity landscape features in order to provide space for wild animals, plants, pollinators and natural pest regulators.

Environmental impacts of agricultural production

The [National Emission-reduction Commitments Directive](#) (NEC Directive) sets national emission-reduction commitments for Member States and the EU for five important air pollutants, including ammonia.

The [Nitrates Directive](#) protects water quality by preventing agricultural nitrates from polluting ground and surface waters and by promoting good farming practices.

The new [EU soil strategy for 2030](#) sets out a framework and concrete measures to protect and restore soils, and ensure their sustainable use.

The [Zero pollution action plan](#) provides a compass to mainstream pollution prevention in all relevant EU policies, to step up implementation of the relevant EU legislation and to identify possible gaps.

The EU has funded research and improved soil monitoring through projects such as [LUCAS](#), a survey on land cover, land use and agri-environmental indicators run by Eurostat, and [Copernicus](#), the EU's Earth Observation and Monitoring Programme.

The EU's [First 'zero pollution' monitoring and outlook](#) shows that the EU is making progress in some areas (in particular where European legislation is well implemented), though pollution levels are still too high and significantly affect health and biodiversity, with more effort needed to reach the 2030 targets.

Zero hunger in the EU: overview and key trends

Malnutrition

A healthy diet means an adequate, well-balanced diet that meets the body's dietary needs.

Combined with regular physical activity and the avoidance of excessive alcohol consumption and tobacco use, a healthy diet is a cornerstone of good health. While ending hunger and all forms of malnutrition are key objectives of the 2030 Agenda, in Europe and in other parts of the world it is obesity that presents the more serious nutrition-related health issue.

More than half of the EU population is overweight and every sixth person is obese

Obesity and pre-obesity are malnutrition problems related to changing consumption and activity habits and environments that favour such unhealthy habits. Combining a balanced nutritional diet with an adequately active lifestyle poses a challenge for many people. While the causes of obesity vary for each person, the problem is generally attributed to unhealthy diets that are high in energy, fat, trans fat and saturated fat, salt and sugar, low in fruit and vegetables, whole grains, legumes and nuts, and too high in red and processed meat. Low physical activity and sociological and hereditary factors are also important causes. The environments, such as the food environment, in which lifestyle choices are made are important determinants of health behaviours and obesity.

Obesity is a significant health issue in the EU, affecting almost 17 % of the adult population in 2019. It is also a contributing factor in other diet-related non-communicable diseases, such as cancer, cardiovascular diseases and diabetes.

Obesity also disproportionately affects people with lower levels of education and generally tends to increase with age until late in life ⁽¹⁾. Childhood obesity also remains an important public health problem in Europe, despite childhood obesity rates levelling off in some European countries ⁽²⁾.

When considered together with pre-obesity, the situation looks even more severe, with more than half of the adult EU population being overweight in 2019. Patterns in the pre-obesity rate follow patterns in the obesity rate, though pre-obesity affected more than twice as many Europeans as obesity (36.2 % of the adult population) in 2019.

Between 2014 and 2019, the share of overweight (obese and pre-obese) people rose slightly, from 51.1 % to 52.7 %. This is largely due to an increase in the share of obese people, from 15.4 % in 2014 to 16.5 % in 2019. At the Member State level, 22 EU countries saw a rise in the obesity rate between 2014 and 2019. The obesity rate was highest in Malta, with 28.7 % in 2019, and lowest in Romania and Italy, with 10.9 % and 11.7 %, respectively.

The obesity rate generally increases with age, peaking at age group 65 to 74 years (22.3 % obese in 2019) and decreasing again for people aged 75 and older. Obesity and pre-obesity rates also appear to be decreasing with higher educational levels, with obesity rates ranging from 11.4 % in 2019 for adults with tertiary education to 20.3 % for adults with lower secondary education or lower. The obesity rate was also lower among younger people aged 18 to 24, with 6.0 % ⁽³⁾.

Sustainable agricultural production

Sustainable agricultural production is a key element in making food systems fair, healthy and environmentally friendly. A concerted effort is needed to foster a food-production system that is based on sustainable agricultural practices

and produces an adequate supply of food. Three indicators are used to monitor the strong interlinkages that agricultural production has with the social, economic and environmental dimensions of sustainability. These are: agricultural income and labour productivity, investment in agricultural research and innovation, and organic farming.

Labour productivity in EU agriculture has increased, as has investment in the future of farming

To ensure its long-term viability, Europe's agricultural sector needs to achieve economic sustainability. **Labour productivity** is an important component of this and can be partially measured using the indicator 'agricultural factor income per annual work unit (AWU)'.

Following a dip during the economic crisis in the late 2000s, agricultural factor income per AWU has been rising in Europe. By 2022 it was 62.9% higher than it was in 2010. This is mainly due to strong growth between 2009 and 2011 and again between 2016 and 2017 as well as 2021 and 2022, driven partly by increased output values (prices and/or yields) and partly by a reduced **labour force** ⁽⁴⁾.

Agricultural factor income per AWU varies considerably between Member States and farm types. It tends to be higher in countries with more mechanised, input-intensive production systems than in countries using more traditional, labour-intensive methods ⁽⁵⁾.

Investment in agricultural research and innovation is crucial for decoupling agricultural productivity from environmental impacts.

62.9 %
growth in EU
agricultural
factor income
per annual work
unit between
2010 and 2022

3.3
billion EUR
in government
support was
spent on
agricultural R&D
in 2021

Such investments also help to keep EU farmers competitive and adaptable to challenges such as climate change and feeding a rising population. Overall in the EU, national government support to agricultural research and development has risen in the short term, growing by 25.0% since 2016 to reach EUR 3.3 billion in 2021.

Organic farming is on the rise across the EU, but the pace needs to quicken to reach the 2030 target

Organic farming is one example of a sustainable agricultural management system. It seeks to limit environmental impacts by using agricultural practices that encourage responsible use of energy and natural resources, maintain or enhance biodiversity, preserve regional ecological balances, increase soil fertility and water quality, encourage high animal welfare standards, and enhance the capacity to adapt to climate change.

In the EU, the share of organic farming in total agricultural area grew by 2.5 percentage points between 2015 and 2020, to 9.1%. Despite this, the take-up of organic farming will need to accelerate significantly to achieve the 25% target by 2030. Across the EU, Austria leads with more than 25% of its agricultural area farmed organically, followed by Estonia and Sweden with levels slightly above 20%, and Italy and Czechia, with levels slightly above 15%. In all other Member States, organic farming was practised on less than 15% of agricultural land in 2020.

The Farm to Fork Strategy also aims to reduce the EU food system's dependency on pesticides and antimicrobials, contributing to zero pollution and biodiversity objectives. According to a **trend analysis by the European Commission**, the use and risk of chemical **pesticides** decreased by 14% between the baseline period of 2015–2017 and 2020 and the use of more hazardous pesticides fell by 26% over the same time span.

9.1 %
of the EU's
utilised
agricultural area
was farmed
organically in
2020

To protect human and animal health, the Farm to Fork Strategy also aims to reduce EU sales of antimicrobials for farmed animals and aquaculture by 50%. The use and misuse of antimicrobials in agriculture contributes to the problem of microbes such as bacteria and fungi becoming antimicrobial resistant, which reduces the effectiveness of such treatments. As of 2021, the EU has achieved an 18% reduction in EU sales of antimicrobials for farmed animals and in aquaculture compared with the 2018 baseline ⁽⁶⁾.

Environmental impacts of agricultural production

Agriculture provides environmental benefits such as the maintenance of specific farmland ecosystems and diverse landscapes, and by providing carbon sinks. However, increases in agricultural productivity and a move towards industrial agriculture practices have contributed to the degradation of environmental conditions and climate change. The environmental impacts of agriculture include nutrient-related pollution, soil erosion and loss of biodiversity.

Excessive nutrient inputs are threatening the environment and water quality

Ammonia emissions and nitrates in groundwater are linked to excessive inputs of nitrogen from agricultural sources such as mineral fertiliser and livestock manure. Manure produced by livestock is rich in nutrients such as nitrogen (ammonia and nitrates) and phosphorus, and is used as a fertiliser alongside chemical fertilisers. If properly treated, its application improves soil structure and enhances soil organic matter content, which positively contributes to carbon sequestration. When mineral fertilisers or manure are not properly handled and spread, however, excess nutrients that are not taken up by plants are released into the environment (as ammonia in air and as nitrates and phosphorus in water). When released into the atmosphere, ammonia pollutes the air and can land on soil and water, where it can harm sensitive vegetation systems, biodiversity and water quality through eutrophication and acidification.

Since the 1990s, Europe has seen significant decreases in ammonia emissions from agriculture due to reductions in livestock density and nitrogen fertiliser use as well as changes in agricultural practices.

In recent years, however, developments have been less clear, with ammonia emissions increasing between 2013 and 2017, only to fall thereafter to a new low of 3.1 million tonnes by 2020. It must be noted that the national and EU totals may mask considerable variations in fertiliser application and livestock densities at regional and local levels. Ammonia emissions from agriculture remain the main nutrient pollutant of concern regarding negative effects on biodiversity ⁽⁷⁾.

The amount of nitrates in EU groundwater has remained stable at around 23 milligrams per litre (mg/L) since 2005. After briefly rising to 23.8 mg/L in 2018, there has been a downward trend in recent years, with the four-year average nitrate concentration reaching 22.6 mg/L in 2020. In addition, hot spots exist where the nitrates concentration is above 50 mg/L, which is the limit set for drinkable water.

Several countries among those with the highest ammonia emissions per hectare of utilised agricultural area in Europe, such as Malta, Belgium and Germany, are also struggling the most with high nitrates levels in groundwater (see Figures 2.10 and 6.8).

The agricultural sector is also responsible for considerable quantities of **greenhouse gas** (GHG) emissions ⁽⁸⁾, accounting for almost 11 % of total GHG emissions in the EU in 2021 ⁽⁹⁾. Agricultural emissions are generally linked to the management of agricultural soils, livestock, rice production and biomass burning. While the EU's total GHG emissions have decreased by about 9 % since

million tonnes
of ammonia
were emitted
from agriculture
in the EU in
2020

An average of
22.6
milligrams
of nitrates were
in each litre of
groundwater in
the EU in 2020

2016 (see the chapter on SDG 13 'Climate action' on page 235), emissions from the agricultural sector have fallen much slower, by less than 2 % over the same period. By 2021 they had reached some 381 million tonnes of **CO₂ equivalent**, which is around 21 % lower than the 1990 level of 483 million tonnes ⁽¹⁰⁾.

Soil erosion remains a major threat, but signs of improvement exist across the EU

Healthy soils are essential for sustainable and productive agricultural systems. Because soils take years to form, they can be considered a non-renewable resource for food production. One of the biggest threats to soil health in Europe is soil erosion, which can be caused by both wind and water. Though erosion is a natural process, inappropriate land management and other human activities can cause it to accelerate to such an extent that soil can be irreversibly lost. The indicator on estimated soil erosion by water provides a measure of the area at risk of severe soil erosion (leading to the loss of more than 10 tonnes of soil per hectare per year).

In the EU, 196 853 square kilometres (km²) of land was at risk of severe soil loss from water erosion in 2016 — an area equal to about 1.5 times Greece's total land area. The risk of severe soil erosion has been decreasing in the EU, in part due to mandatory cross-compliance measures in the EU **Common Agricultural Policy** (CAP). The share of non-artificial erodible area ⁽¹¹⁾ estimated to be at risk of severe soil erosion by water decreased from 6.1 % to 5.3 % between 2000 and 2016.

5.3 %
of EU land was
estimated to be
at risk of severe
soil erosion by
water in 2016

High agricultural productivity can harm biodiversity

Some agricultural landscapes provide valuable and unique habitats for a host of species, both common and threatened. However, biodiversity has suffered under growing pressure from the race to increase productivity and where ecosystem services, which are provided by features that support biodiversity, have not been given economic value or adequate regulatory protection. Species related to agroecosystems are likely to have fared worse without the agri-environmental measures contained in EU policies — primarily the CAP — but measures have not yet been effective enough to halt overall biodiversity loss in agricultural habitats ⁽¹²⁾.

Farmland **bird species** depend on agricultural habitats. Because they are relatively visible, they are a good indicator species for monitoring biodiversity. The common farmland bird index measures the relative abundance and diversity of 39 farmland bird species compared with the 2000 base year compared with the 2000 base year. Between 2006 and 2021, the EU saw dramatic declines of 20.2 % for common farmland birds, continuing a trend visible since 1990. Between 1990 and 2021, common farmland birds declined by 35.9%. Intensive agricultural practices and the use of pesticides have contributed to the loss of wildlife habitats as well as falling populations of insects, which are an important food source for many farmland birds and provide important ecosystem services such as pollination.

Ensure healthy lives and promote well-being for all at all ages

SDG 3 aims to ensure health and promote well-being for all at all ages by improving reproductive, maternal and child health; ending epidemics of major communicable diseases; and reducing non-communicable and mental diseases. It also calls for reducing behavioural and environmental health risk factors.

Health can be defined as 'a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity' (1). Good health is not only of value to the individual as a major determinant of quality of life, well-being and social participation, it is also a basic precondition for general economic growth. Monitoring SDG 3 in an EU context focuses on the topics of healthy lives, determinants of health, causes of death and access to health care. Over the five-year period assessed, the EU has made progress in most health-related indicators analysed here, even though the impacts of the COVID-19 pandemic are now clearly visible in some areas. As such, the healthy life expectancy has declined in the EU in 2020, and the number of people dying from avoidable (preventable) causes has grown. Developments have been more favourable in the other indicators used to monitor healthy lives, causes of death and access to health care. Progress has been particularly strong in reducing the negative impact of certain other causes of (premature) death and in diminishing

self-reported unmet need for medical care. Less progress, however, has been made in improving some of the health determinants examined, such as obesity rate and noise pollution.

Policy context

Healthy lives

The [EU4Health programme](#) is the main financial instrument to fund the Union's health initiatives. Part of the future [European Health Union](#), it will reduce health inequality, improve public health, and boost the EU's capacity to respond to future health crises.

The [Cohesion policy](#) programmes support the public health response to the COVID-19 pandemic. The [European Social Fund Plus \(ESF+\)](#) supports investments in health such as for re-skilling and up-skilling of the health workforce.

The new [EU Global Health Strategy](#) from 2022 aims to improve global health security and defines interrelated priorities in dealing with global health challenges.

Health determinants

[Europe's Beating Cancer Plan](#) addresses cancer through prevention, early detection, diagnosis and treatment, and quality of life of cancer patients and survivors.

Several EU Directives aim to protect citizens from the hazardous effects of smoking, including the [Tobacco Products Directive](#), the [Tobacco Advertising Directive](#) and the [Tobacco Taxation Directive](#).

The [Clean Air Policy Package](#) and the [Zero Pollution Action Plan](#) aim to reduce air, water, and soil pollution.

The [Farm to Fork Strategy](#) aims to promote healthy diets. The [HealthyLifestyle4All](#) campaign aims to link sport and active lifestyles with health, food and other policies.

Causes of death

The European Commission supports Member States in combatting communicable and other diseases through the [EU4Health programme](#) and [Horizon Europe](#).

The [EU road safety policy framework 2021–2030](#) and [Sustainable and Smart Mobility Strategy](#) aim to reduce deaths and serious injuries on the road by 50 % by 2030.

Access to health care

Access to health care is one of the 20 principles of the [European Pillar of Social Rights](#) and its [Action Plan](#). [Directive 2011/24/EU](#) on patient rights in cross-border health care gives EU citizens the right to access care in the EU and to be reimbursed. A [Council Recommendation](#) from 2022 aims to improve access to affordable high-quality long-term care.

The [Strategy for the rights of persons with disabilities 2021–2030](#) aims to ensure that these people participate in economic and social life and enjoy good health and access to health care. To improve care, research and policy-making, the [European Health Data Space](#) promotes access to health data and the development of digital health services.

The European Commission conducts the [State of Health in the EU](#) initiative in close collaboration with the OECD and the European Observatory on Health Systems and Policies. The recurring cycle of monitoring includes, among other products, the 'Health at a Glance: Europe' series, and Country Health Profiles for each EU Member State.

Good health and well-being in the EU: overview and key trends

Healthy lives

The worldwide surge in [life expectancy](#) over the past century is a result of various factors, including reduced [infant mortality](#), rising living standards, improved lifestyles and better education, as well as advances in [health care](#) and medicine. While life expectancy has increased in EU countries over the past few decades, the pace of progress has slowed in recent years in many of those countries. The COVID-19 pandemic resulted in a decline in life expectancy in most EU countries in 2020 and 2021 ^(?). However, while life expectancy gives an objective assessment of how long people can expect to live, it does not show whether people live their lives in good health. Thus, two indicators are now included in the analysis. The first one, [healthy life years](#) at birth, measures the quantity of life spent in a healthy state. The second one measures the share of people with good or very good perceived health, capturing an individual's subjective view of their well-being.

A child born in 2020 could on average expect to live **64.0 years** in a healthy condition

The healthy life expectancy of the EU population has stagnated since 2016, while self-perceived health has improved

In 2020, a child born in the EU could on average expect to live 64.0 years without any severe or moderate health problems. This is the same number of years as in 2016 but 0.6 years lower than at the pre-pandemic peak of 64.6 years in 2019. However, the overall EU figure masks considerable differences between Member States, with healthy life expectancy varying by 19.3 years between countries in 2020. This difference has

become somewhat smaller compared with 2019, when it amounted to 20.2 years.

While healthy life expectancy has stagnated since 2016, self-perceived health has improved in the EU. Between 2016 and 2021, the share of people perceiving themselves to be in good or very good health increased by 1.5 percentage points. In 2021, 69.0% of people in the EU judged their health as either good or very good. However, this share varied strongly across Member States, ranging from 47.9% to 81.2%. Furthermore, slight differences also exist between rural and urban areas. In 2021, the percentage of people who perceived their health to be good or very good was highest in cities (70.7%), slightly above the average in towns and suburbs (69.2%) and lowest in rural areas (66.3%) ^(?). Lastly, the share of persons with activity limitation — a dimension of disability capturing a long-standing limitation to perform usual activities — who perceived their health as being good or very good was significantly lower than the EU average. Only 26.6% of people with a moderate activity limitation and even only 6.6% of people with severe activity limitation perceived their health as being good or very good in 2021 ^(*), while 85.2% of people without activity limitation did so.

69.0% of the EU population perceived themselves to be in good or very good health in 2021

Women have a higher healthy life expectancy than men, but are less likely to assess their health as good

Between 2016 and 2020, the number of healthy life years that women could expect at birth increased by 0.1 years, from 64.4 years to 64.5 years. During the same period, the healthy life years men could expect at birth decreased by 0.1 years — from 63.6

in 2016 to 63.5 years. On the other hand, women were associated with a higher absolute number of healthy life years, and with a higher gain of healthy life years than men. In addition, the gap between the two examined sexes rose from 0.8 years in 2016 to 1.0 years in 2020. In the same year, in about three out of four Member States, women could expect a higher number of healthy life years at birth than men.

Despite their higher healthy life expectancy at birth, women were less likely than men to rate their health as good or very good: 66.6% of women and 71.6% of men perceived their health as being good or very good in 2021 — a gap of 5.0 percentage points.

High excess mortality has reduced life expectancy in the EU

The COVID-19 pandemic considerably affected death rates in EU Member States throughout 2020 and 2021. The population above the age of 60 years, as well as people from socially disadvantaged groups, were especially affected ⁽⁵⁾. Overall, between January 2020 and February 2023, about 1.74 million excess deaths were recorded in the EU and European Free Trade Association (EFTA) countries compared with the average number of deaths registered during the period 2016 to 2019 ⁽⁶⁾. The decrease in life expectancy across the EU caused by the COVID-19 pandemic in 2020 continued in 2021, once again with substantial differences across countries. Life expectancy at birth in the EU continued to decrease by on average 0.3 years between 2020 and 2021, from 80.4 to 80.1 years — after a decrease of 0.9 years between 2019 and 2020 ⁽⁷⁾. The largest reductions in life expectancy in 2021 compared with 2020 were observed in Bulgaria and Slovakia (2.2 years both), followed by Latvia (2.1 years) and Estonia (2.0 years).

Furthermore, men appear to have been affected somewhat more strongly by the pandemic, with a reduction in life expectancy of 1.3 years compared with a reduction of 1.1 years for women in 2021, compared with pre-pandemic figures (2019). Lastly, the effects of the pandemic on the elderly were substantial. The expected remaining life

years at age 65 decreased by 1 year between 2019 and 2021 — from 20.2 to 19.2 years. Both men and women aged 65 were affected, with their remaining life expectancy falling by 1.0 and 0.9 years, respectively ⁽⁸⁾.

Specific population groups have lower life expectancy

While this monitoring report focuses on the life expectancy of the general population, other studies indicate that life expectancy may differ across specific subpopulations. For example, life expectancy estimates based on interviews with more than 8 000 respondents from 11 EU and non-EU countries suggest that Roma people have a substantially lower life expectancy than that of the general population in those countries. The extrapolated time trend for 2017 suggests that Roma men were expected to live 9.1 fewer years than men in the general population. The corresponding estimate for women shows that the life expectancy of Roma women was 11 years lower than that of women in the general population in the countries examined ⁽⁹⁾.

Health determinants

Many factors affect the health of individuals and populations. These include socio-economic factors, the state of the environment, city design, access to and use of health services, and individual characteristics and behaviour ⁽¹⁰⁾. Lifestyle-related risk factors, such as an unhealthy diet, physical inactivity, smoking and excessive alcohol consumption, directly affect citizens' quality of life and life expectancy. These factors also have a negative impact on the health and social systems of EU Member States, government budgets, and economic productivity and growth. The health determinants discussed in the following sections are [obesity rate](#), smoking prevalence and noise pollution. In addition, further factors such as mobility and consumption patterns may also influence all of the health determinants described on the following pages.

More than half of the adult EU population was overweight in 2019

Obesity is a serious public health problem because it significantly increases the risk of chronic diseases, such as cardiovascular disease, type-2 diabetes, hypertension and certain types of cancer. For some individuals, obesity may also be linked to a wide range of psychological problems. From a societal perspective, obesity has substantial direct and indirect costs that put a considerable strain on health and social security systems. Furthermore, being obese or **overweight** from an early age can lead to more health problems in the long term ⁽¹⁾.

In 2019, 16.5 % of the EU population aged 18 or above were obese (with a body mass index equal to or greater than 30) and another 36.2 % were pre-obese (with a body mass index between 25 and 30) ⁽¹²⁾. In total, more than half of the EU population at the age of 18 or above were obese or pre-obese (and therefore overweight). Between 2014 and 2019 the share of both obese and pre-obese people increased by 1.1 and 0.5 percentage points, respectively. The total share of overweight people grew slightly over this period, from 51.1 % in 2014 to 52.7 % in 2019.

The obesity rate generally increases with age, peaking at age group 65 to 74 years (22.3 % obese in 2019) and decreasing again for people aged 75 and older. Moreover, obesity and pre-obesity rates decrease with higher educational levels, with 2019 obesity rates ranging from 11.4 % for people with tertiary education to 20.3 % for people with lower secondary education or lower. The obesity rate was also lower among young people aged 18 to 24, at 6.0 % ⁽¹³⁾. In 2019, there was furthermore a considerable difference between Member States, with values ranging from 10.9 % in Romania to 28.7 % in Malta for obese people aged 18 and over.

Smoking prevalence among the population aged 15 and over has decreased since 2006

Tobacco consumption is considered to be the single most preventable cause of illness and death worldwide. The WHO European Region — that also includes some non-European countries such as Israel, as well as some countries in Central Asia ⁽¹⁴⁾ — has one of the highest mortality rates attributable to tobacco use ⁽¹⁵⁾. Tobacco use is currently the leading cause of 16 % of all deaths among adults aged 30 years and over in Europe, which is above the global average of 12 %. Many of these deaths occur prematurely, which is hardly surprising because many types of cancer and cardiovascular and respiratory diseases are linked to tobacco use ⁽¹⁶⁾.

25%
of the EU
population
aged 15 and
over were
smokers in 2020

Smoking prevalence among the population aged 15 or over fell between 2006 and 2020, from 31 % to 25 %. In 2020, more men (28 %) than women (22 %) reported that they smoke. However, the decline in smoking prevalence is less evident for women than for men, which can partially explain the narrowing gap in life expectancy between the sexes ⁽¹⁷⁾. The age group with the highest prevalence of smokers were those aged 25 to 54 (close to 30 %) followed by younger respondents aged 15 to 24 (20 %) and older people aged 55 years and above (18 %). Lastly, the share of smokers who indicated they have trouble paying bills most of the time is higher than the share of smokers who said they (almost) never have trouble paying bills ⁽¹⁸⁾.

Noise pollution levels in the EU have decreased

Noise exposure reduces life satisfaction and perceived well-being. The WHO identified noise as the second most significant environmental cause of ill health in western Europe after air pollution ⁽¹⁹⁾. The most harmful health

problems — such as those affecting the circulatory system — arise because of interrelated issues including decreased sleep quality and stress reactions in the human body. These issues can lead to premature death ⁽²⁰⁾. In Europe, environmental noise is estimated to contribute to 12 000 premature deaths per year ⁽²¹⁾. Road traffic is the dominant source of environmental noise, but railways, airports and industry also remain important sources of localised noise pollution ⁽²²⁾. [The WHO Environmental Noise Guidelines for the European Region](#) provide recommendations for protecting human health from exposure to environmental noise that originates from various sources.

The EU has made progress towards reducing noise pollution over the past 11 years, with the share of the population feeling affected by noise from neighbours or the street falling from 20.6 % in 2010 to 17.6 % in 2020. Since the assessment of noise pollution is a subjective measure, a fall in the value of the indicator may not necessarily indicate a similar reduction in actual noise-pollution levels ⁽²³⁾. The perception of noise pollution is also unevenly distributed between Member States: the proportion of people suffering from noise in 2020 was smallest in Estonia (8.0 %) and largest in Malta (30.8 %).

Causes of death

[Causes of death](#) are among the oldest medical statistics available and play a key role in the general assessment of health in the EU. The data can be used to determine which preventive and medical curative measures or investment in research might increase a population's life expectancy. The indicators selected for this sub-theme look at deaths due to communicable diseases, avoidable mortality, air pollution and fatal accidents on roads and at work.

17.6 %
of the EU
population
were affected
by noise from
neighbours or
the street in
2020

While recent developments in certain communicable diseases remain positive, the COVID-19 pandemic seems to have led to more avoidable deaths

Avoidable mortality refers to preventable and treatable causes of death, including injuries and drug-related diseases, as well as respiratory and infectious diseases, and some types of cancer. While avoidable mortality had been decreasing until 2019, the COVID-19 pandemic appears to have reversed the trend. Between 2015 and 2020, preventable mortality rose by 8.2 %, from 166.3 per 100 000 persons in 2015 to 180.0 per 100 000 in 2020. This result may be a consequence of the COVID-19 pandemic: health systems operated close to their capacity limits in many EU countries, which might have prevented health care professionals from providing patients with the health care they needed on time, or even at all. On the other hand, treatable mortality decreased by 4.3 %, from 95.9 per 100 000 persons to 91.7 in 100 000, over the same period. In total, avoidable mortality increased by 3.6 % in the EU, from 262.1 per 100 000 persons in 2015 to 271.7 per 100 000 persons in 2020. While the developments were nevertheless positive in many Member States, the gap of 410.6 persons per 100 000 in 2020 between the highest (593.2 in Romania) and the lowest (182.7 in Cyprus) value shows there remains a great deal of variability within the EU.

The objective of reducing the health burden caused by communicable diseases such as HIV, tuberculosis and hepatitis is enshrined in the Sustainable Development Goals. The EU has also committed to helping Member States achieve the

271.7 per
100 000 people
died
prematurely
in the EU due
to avoidable
causes of death
in 2020

1.9 per
100 000 people
died because
of HIV,
tuberculosis
and hepatitis in
the EU in 2020

objectives to eradicate HIV/AIDS and tuberculosis by 2030 and to reduce hepatitis ⁽²⁴⁾. Deaths due to these three diseases have been falling steadily in the EU over the past two decades. While 4.8 out of 100 000 people died from one of these diseases in 2005, the number of deaths had fallen to 1.9 per 100 000 people by 2020. In addition, there was a considerable gap between the country with the highest (7.9 deaths per 100 000 people in Latvia) and the lowest value (0.4 deaths per 100 000 people in Malta) in 2020.

The trends were also positive for the three diseases separately: between 2005 and 2020 deaths per 100 000 people fell from 1.8 to 0.6 for tuberculosis, from 1.3 to 0.4 for HIV/AIDS and from 1.7 to 0.8 for hepatitis. In the case of hepatitis, however, the current calculation of the indicator may conceivably underreport deaths due to hepatitis B and C ⁽²⁵⁾.

The number of premature deaths due to exposure to air pollution by fine particulate matter in the EU has fallen

According to [European Environment Agency \(EEA\) estimates](#), air pollution is the number-one environmental cause of death in Europe. It can lead to or aggravate many chronic and acute respiratory and cardiovascular diseases. Air pollution has been one of the EU's main environmental policy concerns since the late 1970s.

Air pollutants are emitted both naturally and as a result of human activities, mainly through fuel combustion.

Urban populations are particularly exposed because of the daily flow of commuters, and the high concentration of industry and human activities causing the emission of fine particulate matter in EU cities. In addition, the most vulnerable citizens remain disproportionately affected by air pollution ⁽²⁶⁾. For example, groups with lower socio-economic status tend to be disproportionately affected by air pollution because they often live closest to

its source. Children are another disproportionately affected group. On one hand, children have higher respiratory rates than adults, which increases their exposure to air pollution. On the other hand, children's developing immune system and organs make them more vulnerable to air pollution ⁽²⁷⁾. Air pollution also has a significant negative impact on the economy, by reducing both productivity and life expectancy, as well as by increasing health costs ⁽²⁸⁾.

Fine [particulate matter](#) (PM_{2.5}) is one of the most harmful components of air pollution for human health, causing 237 810 premature deaths in Europe in 2020. Between 2005 and 2020, premature deaths due to exposure to PM_{2.5} decreased by 44.8 %. This development suggests the EU is on track to meeting its target of reducing the negative impact of air pollution on health by 55 % by 2030 compared with 2005, as set out in the [Zero Pollution Action Plan](#) (see '[Zero pollution' monitoring and outlook](#)'). However, according to the EEA, it may be challenging for most EU countries to keep reducing the concentration of particulate matter in ambient air over the next decade ⁽²⁹⁾. To ensure the 2030 target is met, Member States need to fully adopt and implement current and proposed EU legislation, notably in the areas of energy and climate, and vehicle emissions. To help accelerate progress, the European Commission published a proposal for the revision of the EU [Directive on ambient air quality and cleaner air for Europe](#) in October 2022 to align air quality standards with the [recommendations of the WHO on air quality](#).

237 810
people
died
prematurely in
the EU in 2020
due to exposure
to PM_{2.5}

Fatal accidents at work and on the road have decreased, but further progress is necessary to meet the 2030 target of halving deaths from road crashes

Accidents were one of the most common causes of death within the EU in 2020, leading to more than 154 000 deaths or 3.0 % of all deaths ⁽³⁰⁾. These accidents may happen at different places such as at home, leisure venues or work, as well as while travelling. Improving the working environment to protect employee health and safety is an important objective set out by the

EU and its Member States in the [Treaty on the Functioning of the European Union](#).

Halving the number of deaths from road-traffic crashes is not only a global target, but also a goal of EU policies. The [EU road safety policy framework 2021–2030](#) set a target of reducing deaths and serious injuries by 50% by 2030 compared with 2019.

In 2021, slightly more than 19 900 people were killed in road traffic crashes (equalling 4.5 per 100 000 people). This represents a 16.3% reduction compared with 2016, due in part to the lower traffic volumes as a result of the COVID-19 pandemic. However, the number of road fatalities in the EU will need to fall more quickly to meet the target of halving the number of people killed in road traffic crashes by 2030 compared with 2019 levels. The EU rate of 4.5 fatalities per 100 000 people compares favourably with the global average of around 18 per 100 000. Preliminary results for 2022 indicate that fatalities remained well below the pre-pandemic level: while in 2022 road deaths rose by 3% in relation to 2021, they remained almost 10% lower compared with the pre-pandemic year 2019 ⁽³¹⁾. For further details see the chapter on SDG 11 'Sustainable cities and communities' on page 203.

**4.5 per
100 000 people
were killed in
road crashes in
the EU in 2021**

Fatal accidents, leading to a person's death within one year, may also occur at work. The EU made progress on this indicator between 2015 and 2020, reducing the number of [fatal accidents at work](#) per 100 000 employed persons from 2.0 to 1.8. Compared with 2019, the total incidence rate for fatal accidents at work increased somewhat in 2020. The reason for this increase might be that some countries included COVID-19 cases in the reported data on fatal work accidents ⁽³²⁾. Furthermore, there is a considerable

**1.8 per
100 000
persons
employed
had a fatal
accident at work
in the EU in
2020**

difference between the sexes: the incidence rate for women (0.3) was negligible compared with the rate for men (3.1). This difference can be explained by the higher share of men working in professions associated with a higher risk of work accidents. Non-fatal accidents can also cause considerable harm, for example by leading to a permanent [disability](#) that may force people to leave the labour market or change their job. Non-fatal accidents happened considerably more often than fatal accidents, with an incidence rate of 1 444 per 100 000 employed persons in 2020 ⁽³³⁾.

Access to health care

Access to health care — the timely access to affordable, preventive and curative health care — is high on the political agenda of most EU countries. It is defined as a right in the Charter of Fundamental Rights and is one of the 20 principles of the [European Pillar of Social Rights](#) ⁽³⁴⁾. Limited access for some population groups, especially people with disabilities, may result in poorer health outcomes and greater health inequalities ⁽³⁵⁾. Reducing health inequalities is not only important for equity reasons, but also because it contributes to higher economic and social cohesion ⁽³⁶⁾.

Overall, the unmet need for medical care has decreased, but the gap between Member States has widened

In 2021, 2.0% of the EU population reported an unmet need for medical care because of financial reasons, long waiting lists or travel distance. This share was lower than five years earlier, when it was 2.8%. However, progress seems to have stalled since 2017, and in some Member States the trend has reversed, showing an increase in the percentage of the population that reported unmet medical need in 2021 — a trend that started in 2019. The considerable differences between Member States' reported unmet needs

**2.0%
of the EU
population
reported
unmet need for
medical care in
2021**

for medical care registered in 2016 have become substantially smaller five years later. Compared with 2016, the gap between the EU countries has narrowed by 7.1 percentage points, reaching 8.0 percentage points in 2021. While in Cyprus, Germany and Malta, 0.1 % of the population reported an unmet need for medical care in 2021 for the reasons monitored, in Estonia the rate was 8.1 % of the population.

Moreover, people with disabilities find it more difficult to access health care. In 2021, 6.2 % of people with severe activity limitations and 3.9 % of people with some activity limitations reported unmet needs for medical care due to the monitored reasons (financial, waiting list or distance), compared with only 1.1 % of people without disabilities ⁽³⁷⁾. This discrepancy indicates that access to health care remains a challenge not only in certain parts of the EU but also for certain population groups.

Financial constraints are the most common reason why people report unmet needs for medical examination. On average, for 1.0 % of the total EU population in 2021, 'too expensive' was the most prominent reason for reporting unmet medical examination. Furthermore, financial constraints were the most common self-reported reason for unmet needs in rural areas (1.1 %), which was slightly more than for people in towns or suburbs (0.9 %) and in cities (0.8 %). A further 0.9 % across all degrees of urbanisation reported 'waiting lists' as a reason for unmet need for medical examination. This reason for unmet medical needs was more often declared in cities, and rural areas (both 1.0 %) than in towns and suburbs (0.8 %). Another 0.1 % described 'too far to travel' as the main reason for an unmet need for medical examination. This was more often the case in rural areas (0.2 %) than in cities, or in towns and suburbs (both 0.1 %). However, not all Member States listed cost as the main reason for unmet need — in many countries waiting lists were cited by the majority of people ⁽³⁸⁾.

Most European countries have achieved universal coverage for a core set of services, which usually include consultations with doctors, tests, examinations and hospital care. Yet in some countries, coverage of these services may not

be universal or patients may have to bear the costs of accessing them. Furthermore, across the EU, around a seventh of all health spending was borne directly by households in 2020. Out-of-pocket payments as a share of total current health expenditure decreased slightly from 15.9 % in 2014 to 14.4 % in 2020. However, a considerable gap of 27.1 percentage points between countries remained in 2020 ⁽³⁹⁾. Such out-of-pocket payments can pose a serious problem for low-income households, in particular if combined with reduced financial resources for the health care system caused, for example, by an economic crisis ⁽⁴⁰⁾. Moreover, across Member States, between 1.0 % and 19.2 % of households experienced catastrophic spending on health, meaning out-of-pocket spending on health care exceeded 40 % of a household's disposable income ⁽⁴¹⁾. Poor households and those who have to pay for long-term treatment such as medicines for chronic illness are at high risk of experiencing financial hardship as a result of having to pay out of their own pockets.

Specific population groups may not have the same access to health services as the general population

In many EU countries minorities do not have the same access to health services as the general population. One of those minorities is the Roma people. According to a [study based on survey data from 2021](#) the share of Roma people who experienced discrimination in terms of access to health services increased between 2016 and 2021 in most of the 13 EU and non-EU countries examined by the Fundamental Rights Agency. The same survey provides evidence that women were more often discriminated against than men. Furthermore, the youngest and the oldest respondents reported lower levels of discrimination compared with middle-aged respondents: the age group 16 to 24 experienced discrimination in 10 % of cases, while respondents aged 65 and above reported discrimination in 13 % of cases. At the same time, 16 % of respondents aged 25 to 64 reported they had experienced discrimination.

4

Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all

SDG 4 seeks to ensure access for all to quality education through all stages of life, as well as to increase the number of young people and adults who have the relevant skills for employment, decent jobs and entrepreneurship.

Education and training are key drivers for growth and jobs because they help to improve employability, productivity, innovation and competitiveness. In the broader sense, education is also a precondition for achieving many other SDGs. Monitoring SDG 4 in an EU context focuses on basic education, tertiary education, adult learning and digital skills. Over the assessed five-year period, the EU has made significant progress in increasing participation in basic and tertiary education as well as in adult learning and to a lesser extent in early childhood education. In contrast, trends in educational outcomes have been less favourable. The percentage of underachievers in the PISA test has further deteriorated, and the share of adults with at least basic digital skills remains far from its target.

Table 4.1: Indicators measuring progress towards SDG 4, EU

Indicator	Period	Annual growth rate	Trend	Where to find out more
Basic education

Note: See Annex I for a description of the methodology used for the growth rate calculation and the trend assessment. For indicators without a target, the growth rates observed over the specified periods are given. For indicators with a quantified EU target, both the observed growth rates and the growth rates that would have been required in the specified periods for meeting the target are given.

⁽¹⁾ Trend refers to worst performance among the three subjects (science).

⁽²⁾ Trend refers to worst performance among the three subjects (reading).

Policy context

The [European Education Area \(EEA\)](#) is the EU's policy and investment framework in the area of education that helps Member States and the wider education community work together to build more resilient and inclusive education and training systems.

Basic education and tertiary education

Four out of the seven [EEA strategic framework](#) targets to achieve by 2030 are used to monitor progress in basic and tertiary education in the EU: at least 96 % of children between the age of 3 and the starting age for compulsory primary education should participate in early childhood education and care; less than 9 % of pupils should leave education and training early; less than 15 % of 15-year-olds should be low-achievers in reading, mathematics and science; and at least 45 % of 25–34-year-olds should have a tertiary education qualification.

Basic and tertiary education are supported by the [European Social Fund Plus](#) and the [European Child Guarantee](#). Additionally, the [reinforced Youth Guarantee](#) aims to ensure that all young people under the age of 30 receive an offer of good quality employment, continued education, apprenticeship and traineeship within a period of four months of becoming unemployed or leaving education.

The [Erasmus+ programme](#) focuses on quality and inclusive education with a commitment of more than EUR 26 billion for 2021 to 2027.

Adult learning and digital skills

The new [European Skills Agenda](#) aims to help individuals and businesses develop more and better skills and to put them to use. A [Council](#)

[Resolution on a new European agenda for adult learning 2021–2030](#) from 2021 highlights the need to significantly increase adult participation in formal, non-formal and informal learning. The European Commission responded to the new skills demand in Europe by declaring 2023 to be the [European Year of Skills](#) and promoting a mind-set of lifelong skills development. The EEA requires that by 2025 at least 47 % of adults aged 25 to 64 will have participated in learning during the past 12 months, while the EU leaders have endorsed a headline target proposed by the [European Pillar of Social Rights Action Plan](#) that by 2030 at least 60 % of all adults should be participating in training every year.

The EEA also sets the target that by 2030 less than 15 % of eighth-graders should be low-achievers in computer and information literacy. The [Digital Education Action Plan \(2021–2027\)](#) supports the sustainable and effective adaptation of the education and training systems of Member States to the digital age. The plan contributes to achieving the goals of the [European Pillar of Social Rights Action Plan](#) and the '2030 Digital Compass: the European way for the Digital Decade', which both have a goal for at least 80 % of people aged 16–74 to have basic digital skills.

Furthermore, the [Digital Europe Programme \(DIGITAL\)](#) is the first EU financial instrument designed to bring digital technology to businesses and citizens. It focuses on building the strategic digital capacities of the EU and on facilitating the wide deployment of digital technologies.

In addition, also the [Recovery and Resilience Facility](#) supports reforms and investments in general, vocational, and higher education as well as digital skills.

Quality education in the EU: overview and key trends

Basic education

Basic education covers the earliest stages in a child's educational pathway, ranging from early childhood education and care to primary and secondary education. An inclusive and quality education for all, which eliminates school segregation, is an essential element of sustainable development. SDG 4 thus aims to ensure that by 2030 all girls and boys have access to quality early childhood development, care and pre-primary education so they are ready for primary education. In addition, SDG 4 intends to ensure that all boys and girls complete free, equitable and quality primary and secondary education leading to relevant and effective learning outcomes. Furthermore, SDG 4 focuses on ensuring that all youths have the literacy, numeracy and relevant skills needed for employment, decent jobs and entrepreneurship.

Participation in early childhood education and care is rising too slowly in the EU to meet the 2030 target

Early childhood education and care is usually the first step on a child's educational pathway. According to the [EU Quality Framework for Early Childhood Education and Care](#), access to quality early childhood education and care for all children contributes to their development, well-being and educational success. Also, as highlighted in the 2022 [Council Recommendation on early childhood education and care](#), the absence of early childhood education and care is a significant constraint on female labour market participation.

93.0%
of young
children in the
EU participated
in early
childhood
education and
care in 2020

The [2021 Council Recommendation on a European child guarantee](#) also emphasise the importance of equal access to quality and inclusive early childhood education and care for breaking the transmission of social exclusion and securing equal opportunities for children in a disadvantaged situation. Tackling disadvantage from early years is a cost-effective investment as it contributes to the inclusion of children and their integration into the labour market and social life when they are adults.

[Participation in early childhood education](#) is defined as the share of the population aged between three years and the starting age of compulsory primary education who take part in early education. Participation in early childhood education has risen slowly in the EU since 2014, reaching 93.0% in 2020. Stronger progress will be necessary in the coming years to meet the target of 96% by 2030.

Educational attainment levels in the EU are improving

Early school leaving is linked to unemployment, social exclusion, poverty and poor health. Thus, it is in the interest of societies as a whole, as well as individuals themselves, to make sure that everyone completes a certain level of education and training. Consequently, the [EEA strategic framework](#) has set a target to reduce the share of early leavers from education and training (ELET) to below 9% by 2030.

9.6%
of people aged
18 to 24 had left
education and
training early in
the EU in 2022

Since 2002, the ELET rate has fallen continuously in the EU, albeit more slowly in recent years. In 2022 the share had reached 9.6%, putting the EU well on track to meeting the 2030 target. An analysis

by degree of urbanisation reveals that young people living in towns and suburbs (10.6%) and rural areas (10.0%) were more likely to leave school early than young people living in cities (8.6%) in 2022 ⁽¹⁾. For further analyses of ELET trends by sex and citizenship, see the chapters on SDG 5 'Gender equality' on page 103 and on SDG 10 'Reduced inequalities' on page 183.

Monitoring of the 9% target is complemented by a supplementary indicator on the completion of at least upper secondary education, which is generally considered the minimum requirement for gaining satisfactory employment in today's economy and is important for full participation in society. The indicator, which measures the share of people aged 20 to 24 with at least an upper secondary qualification, shows that 83.6% had completed this level of education in 2022 ⁽²⁾.

Educational outcomes in reading, maths and science have continued to deteriorate

Besides educational attainment in general, achieving a certain level of proficiency in basic skills is a key objective of all educational systems. Basic skills, such as reading a simple text or performing simple calculations, provide the foundations for learning, gaining specialised skills and personal development. Low achievers in the OECD's Programme for International Student Assessment (PISA) are those pupils who fail to reach the minimum proficiency level necessary to participate successfully in society. These pupils face having fewer opportunities in future, at both the personal and the professional level ⁽³⁾.

In 2018, more than one in every five 15-year-old pupils showed insufficient abilities in one or more of these basic skills. Test results in that year showed 22.3% of pupils were low achievers in science, followed by 22.5% for reading and 22.9% for mathematics ⁽⁴⁾. Compared with 2015, the results were a step backward, indicating the EU is lagging

seriously behind in all three domains when it comes to reaching the 2030 EU-level target of reducing the share of low-achieving 15-year-olds in basic skills to less than 15%.

Tertiary education

Continuing education after the basic level is important because people with higher qualifications are more likely to be employed and less likely to face poverty in a knowledge-based economy. Therefore, investing efficiently in education and training systems that deliver high-quality and up-to-date services lays the foundation for a country's prosperity. Moreover, employment rates are generally higher for highly educated people. Conversely, low levels of tertiary educational attainment can hinder competitiveness, innovation and productivity and undermine growth potential.

The share of people with tertiary education has increased significantly since 2002

The [EEA strategic framework](#) aims to raise the share of the population aged 25 to 34 that has completed a higher education qualification (levels 5–8 in the 2011 [International standard classification of education](#), ISCED) to at least 45% by 2030. As a result of an 18.9 percentage point increase since 2002, the EU reached a tertiary education attainment rate of 42.0% in 2022 and is well on track to meeting its 2030 target. The degree of urbanisation seems to be related to tertiary attainment levels. While in 2022 more than half (52.2%) of the population aged 25 to 34 living in cities had attained tertiary education, the rate was significantly lower for towns and suburbs (35.9%) and rural areas (30.2%) ⁽⁵⁾.

22.5 %
of 15-year-old
pupils in the
EU showed
insufficient
reading skills in
2018

42.0 %
of the EU
population
aged 25 to 34
had attained
tertiary
education in
2022

The share of 25- to 34-year-olds with tertiary education has been growing steadily since 2002 in all Member States. This partly reflects their investment in higher education to meet the demand for a more skilled labour force. Moreover, some countries shifted to shorter degree programmes following the implementation of the [Bologna process](#) reforms. For further analyses of the trends in tertiary education by sex, see the chapter on SDG 5 'Gender equality' on page 103 and on SDG 9 'Industry, Innovation and Infrastructure' on page 165.

Adult learning

Keeping skills up to date to support the ongoing quest for a high-quality labour force is one of the goals of adult learning. [Adult education](#) covers the longest period in a person's learning lifetime. It is crucial for maintaining good health, remaining active in the community and being fully included in all aspects of society. Moreover, it helps to improve and develop skills, adapt to technological developments, advance a person's career or aid their return to the labour market (upskilling and reskilling).

Adult participation in learning is growing

Adult participation in learning monitors the share of people aged 25 to 64 who stated they received formal or non-formal education and training in the four weeks preceding the survey. While this share has grown since 2002, when it stood at 5.3 %, it has remained at a rather low level, reaching just 11.9 % in 2022. A drop to 9.1 % in 2020 might be related to the COVID-19 pandemic and the adjustments to the related contingency measures, such as lay-offs and teleworking. Similarly, for adults not in employment, enrolment into education and training programmes reduced temporarily during the beginning of the pandemic due to extended lockdown periods.

11.9 %
of 25- to
64-year-
old adults
participated in
learning in the
EU in 2022

Women are more likely to participate in adult learning than men. In 2022, the share of 25- to 64-year-old women was 2.1 percentage points higher than that for men (12.9 % compared with 10.8 %, respectively). The rate for women was not only higher than for men, it had also been improving faster, gaining 7.4 percentage points since 2002, compared with 5.8 percentage points for men. The participation rate in adult learning also differs in terms of degree of urbanisation. In 2022, adults living in cities were more likely to participate in learning (14.6 %) than those living in towns and suburbs (10.6 %) or rural areas (9.0 %) ⁽⁶⁾.

While the above-mentioned indicator is based on the question of whether adults participated in learning during the four weeks preceding the survey, the target defined in the [EEA strategic framework](#) and the [European Pillar of Social Rights Action Plan](#) refers to the share of adults participating in learning during the past 12 months. Baseline data for the target definition have so far only been collected in 2016 ⁽⁷⁾. At that time, the share stood at 37.4 %, which is 9.6 percentage points below the EU target of 47 % for 2025 and 22.6 percentage points below the 2030 target of 60 %. Participation rates were particularly low for low-educated adults (ISCED 2011 levels 0–2), at 17.9 %. The [European Skills Agenda](#) consequently also set a target for raising the share of adults aged 25 to 64 with low qualification and who participated in learning during the past 12 months to 30 % by 2025. In contrast to this group, more than half (58.1 %) of adults with tertiary education (ISCED 2011 levels 5–8) participated in learning in 2016.

Digital skills

Digitalisation is having a massive impact on the labour market and the type of skills needed in the economy and society. Thus, digital skills are of critical value for working, learning and social interaction. The COVID-19 pandemic accentuated the digital skills gap that already existed and new inequalities are emerging as many people still do not have a basic level of digital skills or are in workplaces or schools that are lagging behind in digitalisation.

The share of people with at least basic digital skills remains far from the 2030 target

The [European Pillar of Social Rights Action Plan](#) has set a complementary target for the EU to raise the share of people aged 16 to 74 who have at least basic digital skills to 80% in 2030. This target is monitored using the composite indicator for digital skills, based on selected activities performed by individuals on the internet in specific areas: information and data literacy, communication and collaboration, digital content creation, safety and problem solving. The level of 'at least basic digital skills' refers to the two highest out of six levels derived from the survey on the use of information and communication technologies (ICT) in households and by individuals. It is assumed that individuals who can perform certain activities have the desired digital skills, therefore the indicator can be considered as a proxy for the digital competences and skills of individuals.

In 2021, the share of people aged 16 to 74 with at least basic digital skills stood at 53.9% and thus at a level considerably below the 80% target for 2030. In contrast to most other education

53.9 %
of 16- to
74-year-old
people in the
EU had at least
basic digital
skills in 2021

indicators presented in this chapter, fewer women (52.3% in 2021) had at least basic digital skills than men (55.6%). Age and formal education also affect a person's level of digital skills. While 71.2% of 16- to 24-year-olds had basic or above-basic overall digital skills in 2021, this was only the case for 62.1% of 25- to 54-year-olds. Older people struggle in particular with the use of digital media, with only 34.6% of people aged 55 to 74 having at least basic digital skills in 2021. Additionally, 79.0% of people with high formal education had such digital skills in 2021, while this was only the case for 31.9% of people with no or low formal education ⁽⁸⁾.

Digital competences constitute an essential skill for participating in a technology-driven world. In the [EEA strategic framework](#), the EU sets a target for the share of low-achieving eighth-graders in computer and information literacy to be less than 15% by 2030. One of the key findings of the 2018 study shows that young people do not develop sophisticated digital skills just by growing up using digital devices: in 8 out of 13 Member States participating in the [International Computer and Information Literacy Study \(ICILS\)](#), more than one-third of pupils achieved scores below level 2 on the ICILS CIL scale. This level can be defined as the threshold for underachievement in digital competence ⁽⁹⁾.

5

Achieve gender equality and empower all women and girls

SDG 5 aims to achieve gender equality by ending all forms of discrimination, violence and any harmful practices against women and girls. It also calls for the full participation of women and equal opportunities for leadership at all levels of decision-making.

Ending all forms of discrimination against women and girls and empowering women are crucial to accelerating sustainable development in the EU. Thus, monitoring SDG 5 in an EU context focuses on the topics of gender-based violence, access to quality education, participation in employment, equal payment and a balanced representation in leadership positions. Over the assessed five-year period, the EU has made strong progress in most of these areas. The gender gaps for certain labour market-related indicators have narrowed, even though stronger progress will be needed to reach the 2030 target of halving the gender employment gap. Moreover, the EU has improved in terms of women occupying leadership positions, but differences between women and men remain far from parity. The situation is reversed in the area of participation in education. While the gender gap for early school leaving is narrowing, men continue to fall further behind women in terms of tertiary educational attainment levels.

Table 5.1: Indicators measuring progress towards SDG 5, EU

	2017–2022	5.1 %	↑	

Note: See Annex I for a description of the methodology used for the growth rate calculation and the trend assessment. For indicators without a target, the growth rates observed over the specified periods are given. For indicators with a quantified EU target, both the observed growth rates and the growth rates that would have been required in the specified periods for meeting the target are given.

(*) Multi-purpose indicator.

(!) Gender gap is widening to the disadvantage of men.

Policy context

The [EU Gender Equality Strategy 2020–2025](#) presents policy objectives and actions to make significant progress towards a gender-equal Europe by 2025. The goal is that women and men, as well as girls and boys, are free to pursue their path in life, have equal opportunities to thrive and can equally participate in and lead European society.

Under [EU Cohesion Policy](#), Member States have to ensure that equality between men and women, gender mainstreaming and the integration of a gender perspective are taken into account and promoted throughout the preparation, implementation, monitoring, reporting and evaluation of programmes.

Under the [European Social Fund Plus \(ESF+\)](#), Member States have the obligation to programme targeted actions to promote gender equality, equal opportunities and non-discrimination, including in addressing gender-based violence, ensuring access to education and employment, as well as promoting social inclusion.

Gender-based violence

The benchmark for international standards in gender-based violence is the [Istanbul Convention](#), which the EU signed in 2017, and the [EU Strategy on victims' rights](#) (2020–2025) which guarantees that all victims of crime can fully rely on their rights, no matter where in the EU the crime took place. Ending gender-based violence is one of the key objectives of the [EU Gender Equality Strategy 2020–2025](#). It is also a subject of the [European Parliament resolution on the situation of women with disabilities](#).

Education

The [Strategic framework for European cooperation in education and training \(2021–2030\)](#) prioritises improving quality, equity, inclusion and success for all in education and sets a monitoring framework via policy targets to be achieved by 2030.

Employment

A [proposal on pay transparency](#) is aimed at ensuring women and men in the EU get equal pay for equal work.

The [European Pillar of Social Rights Action Plan](#) proposes a new EU headline target of raising the overall employment rate to at least 78 % by 2030. This includes the complementary target of halving the gender employment gap by 2030 compared with 2019 levels.

The [Work-life Balance Directive](#) aims to help women and men reconcile work and caring responsibilities and promote gender equality.

Leadership positions

Achieving gender balance in decision-making and in politics is a priority area for the European Commission and another key objective of the [EU Strategy of Gender Equality 2020–2025](#). The [Women on Boards' Directive](#) seeks to improve the gender balance in corporate decision-making positions in the EU's largest listed companies. The Directive proposes a target for the under-represented sex to make up 40 % of non-executive board members or 33 % of all directors by 2026.

Gender equality in the EU: overview and key trends

Gender-based violence

Gender-based violence is a brutal form of discrimination and a violation of fundamental human rights. It is both a cause and a consequence of inequalities between women and men. Physical and [sexual violence](#) against women affects their health and well-being. Moreover, it can hamper women's access to employment and harm their financial independence and the economy overall.

One in three women in Europe has experienced physical and/or sexual violence since the age of 15

In 2012, a survey from the European Union Agency for Fundamental Rights (FRA) revealed that 8 % of women in the EU had experienced physical and/or sexual violence by a partner or non-partner in the 12 months prior to the interview. Younger women were more likely to report having been subjected to violence; 12 % of women aged 18 to 29 had experienced physical or sexual violence in the 12 months prior to the interview, whereas 5 % of women aged 50 to 59 had been affected. Over a longer time period, every third woman (33 %) in the EU reported having experienced physical or sexual violence since the age of 15 in the FRA survey from 2012 ⁽¹⁾. In 2022, Eurostat published the first results of a new [EU survey on gender-based violence against women](#). While the full sample of this new data collection is not yet available, the released data for the first batch of countries show that in France, Austria and the Netherlands more than a third of women have experienced physical or sexual violence during

8 %
of women
in the EU in
2012 had
experienced
physical or
sexual violence
during the past
12 months

their adulthood, with the highest share of more than 40 % in the Netherlands ⁽²⁾. Women with disabilities are even more likely to be a victim of physical and/or sexual violence, at a rate that is two to five times higher than the rate for women without disabilities ⁽³⁾.

Data from official crime statistics on intentional homicide and sexual offences show that women are much more likely to be a victim of such crimes than men. In 2020, 49 out of 100 000 women were victims of sexual assault, and 28 out of 100 000 women were victims of rape. The rates were significantly lower for men, with 9 per 100 000 men for sexual assault and 3 out of 100 000 men for rape ⁽⁴⁾. Moreover, women are about twice as likely as men to be a victim of intentional homicide by family and relatives or their intimate partner. In 2020, 0.4 out of 100 000 women were victims of such homicide, compared with only 0.2 per 100 000 men ⁽⁵⁾. In Western Europe this type of homicide notably increased during the pandemic ⁽⁶⁾.

The prevalence of violence varies greatly across the EU. However, caution is needed when comparing countries' official crime statistics. Their comparability can be affected, for example, by different legal and criminal justice systems or criminal law and legal definitions such as those concerning offenders, victims or prosecutable age. Also, aspects such as the organisation and efficiency of the police, prosecution and courts or recording and reporting systems contribute to cross-country differences ⁽⁷⁾. The limitations of comparability also include the stigma associated with disclosing cases of violence against women in certain settings and to certain people, including to interviewers. In addition, Member States that rank highest in terms of gender equality also tend to report a greater prevalence of violence against women. This may indicate a greater awareness and willingness of women in these countries to report violence to the police or to an interviewer ⁽⁸⁾.

Education

Education is a driving force for social change and a condition for the achievement of fundamental human rights. Also, equipping people with the right skills allows them to find quality jobs and improve their chances in life and thus combat the risks of social exclusion. Economic independence also makes it easier to leave a difficult situation, such as a violent home ⁽⁹⁾. In education and training, it is important to eliminate gender stereotypes and promote gender balance in traditionally 'male' or 'female' fields. In general, equal access to quality education and training is thus an important foundation for gender equality and an essential element of sustainable development.

Young women outperform men in terms of education

Women overall tend to perform better than men when it comes to early leaving from education and training in the EU. In 2022, 11.1 % of men and 8.0 % of women aged 18 to 24 had left education and training earlier, meaning with at most lower secondary education while not being in further education and training. Although this gap narrowed between 2002 and 2016, it widened again over the following four years. Since 2020, women's early leaving rate has stagnated at 8.0%, while the rate for men fell by 0.8 percentage points. As a result, the gender gap in 2022 was slightly below the value recorded five years earlier, but remained substantial, at 3.1 percentage points.

A major expansion in higher education systems has taken place in the EU since the early 2000's, when the [Bologna process](#) put in motion a series of reforms to make European higher education

The rate of early leavers from education and training among men in the EU was 11.1 percentage points higher than among women in 2022

more compatible, comparable, competitive and attractive for students. As a result, the share of the population aged 25 to 34 who completed tertiary education increased steadily between 2002 and 2022. The increase was particularly strong for women, whose tertiary educational attainment rate rose from 25.3 % in 2002 to 47.6 % in 2022. For men, the increase was slower, from 21.0 % to 36.5 %. This caused the gender gap to surge from 4.3 percentage points to 11.1 percentage points between 2002 and 2022.

The tertiary educational attainment rate of women in the EU was 11.1 percentage points higher than for men in 2022

Employment

Ensuring high employment rates for both men and women is one of the EU's key targets. Reducing the wide gender employment gap, which measures the difference between the employment rates of men and women aged 20 to 64, is important for equality and a sustainable economy. The [European Pillar of Social Rights Action Plan](#) consequently includes the target of at least halving the gender employment gap by 2030 compared with 2019.

Women tend to be more highly educated than men in most EU countries. Despite this, women are still paid less, as evidenced by the persistent [gender pay gap](#). Women in the EU are over-represented in low-paid sectors and under-represented in well-paid sectors. Because of the gender pay gap, and interrupted and shorter working lives, women earn less over their lifetime than men. The correlation between women's lower employment rate and caring responsibilities aggravates women's risk of poverty and social exclusion, especially in old age, as employment and pay gaps largely influence the [gender pension gap](#).

6

Ensure availability and sustainable management of water and sanitation for all

SDG 6 calls for ensuring universal access to safe and affordable drinking water, sanitation and hygiene, and ending open defecation. It also aims to improve water quality and water-use efficiency and to encourage sustainable abstractions and supply of freshwater.

Access to water is a basic human need. Provision of drinking water and sanitation services is a matter of public and environmental health in the EU. Clean water in sufficient quantity is also of paramount importance for agriculture, industry and the environment and plays a crucial role in providing climate-related ecosystem services. Monitoring SDG 6 in an EU context focuses on sanitation, water quality and water scarcity. While the EU has made further progress on access to sanitation, trends for water quality have been mixed over the assessed five-year period, with concentrations of some surface and groundwater pollutants rising. Similarly, despite an overall positive long-term trend, developments regarding water scarcity have been mixed, with seasonal variations and a slight decline in recent years that can be attributed to more frequent and severe drought events.

Policy context

Sanitation

Protection of water resources, water ecosystems, and drinking and bathing water is a cornerstone of EU water policy, as proposed in the [8th Environment Action Programme](#).

The [Urban Waste Water Treatment Directive](#) regulates the collection, treatment and discharge of domestic and industrial urban waste waters. The Directive is currently being revised by the European Commission.

The [European Pillar of Social Rights](#) lists water and sanitation among the essential services that everyone should have access to. In 2023, the Commission will release a first EU Report on Access to Essential Services that provides a state of play concerning access to the essential services including access to water and sanitation.

Water quality

The [Water Framework Directive](#) is the main European legislation aiming to protect and restore water bodies and to prevent and/or limit deterioration by excessive abstractions or pollution. As part of the [Zero Pollution package](#), the Commission adopted a proposal in October 2022 to revise the lists of surface and groundwater pollutants. The proposal entails changes in parts of the Water Framework Directive and its daughter directives, the [Environmental Quality Standards Directive](#) and the [Groundwater Directive](#).

The [Nitrates Directive](#) includes measures to prevent nitrates from agriculture polluting ground and surface waters by improving the nitrogen balance.

The [Farm to Fork Strategy](#) addresses these challenges by setting objectives to reduce nutrient loss from fertilisers (especially nitrogen and phosphorus) by at least 50% by 2030.

The [Towards Zero Pollution for Air, Water and Soil](#) action plan released in May 2021 sets out key actions to speed up water pollution reduction.

The [Bathing Water Directive](#) requires Member States to monitor and assess bathing water for at least two parameters of (faecal) bacteria. The Directive is currently being reviewed by the European Commission.

Water scarcity

The [EU strategy on adaptation to climate change](#) aims to reduce water use and encourage water efficiency and savings, while guaranteeing a stable and secure drinking water supply.

The [Water Framework Directive](#) aims to ensure water is used and managed in a sustainable way. To reduce water stress and promote water resource efficiency, a new [Regulation on minimum requirements for water reuse for agricultural irrigation](#) entered into force in June 2020. The new rules will apply from June 2023.

Clean water and sanitation in the EU: overview and key trends

Sanitation

Provision of drinking water and the adequate treatment of sewage are matters of public and environmental health. As a vital resource, water is considered a public good in the EU. Water utilities are subject to strict regulation regarding the quality and efficiency of services. The indicators chosen to monitor sanitation are the share of the population having neither a bath, nor a shower, nor indoor flushing toilet in their household and the share of the population connected to at least secondary **waste water** treatment.

Most EU citizens have access to basic sanitation and are connected to secondary waste water treatment

Overall, connection rates and the quality of water services in the EU were already high more than 10 years ago, and have continued to improve. The share of the population without a bath, shower, or indoor flushing toilet in their household fell from 2.2 % in 2015 to 1.5 % in 2020. Data also show that the share of the EU population connected to secondary waste water treatment has increased continuously since 2000, reaching 81.1 % in 2020.

Conventional primary waste water treatment mainly removes suspended solids and only reduces organic water pollution by 20–30 %. Secondary treatment processes, which are typically applied after primary treatment, remove about 70 % of organic pollution. Growth in the share of people connected to secondary treatment indicates that the Urban Waste Water Treatment Directive, which was first implemented in the 1990s, has helped to reduce pollution and

1.5 %
of the EU
population
lacked sanitary
facilities at
home in 2020

improve water quality in Europe's rivers, lakes and coastal waters. The ongoing revision of the Directive will bring additional improvements not only for water quality but also for access to sanitation.

Different levels of access to water services and sanitation persist between Member States

Almost every household in the EU had basic sanitary facilities in 2020, and most countries reported that less than 1 % of their population were still living in households without a bath, shower or a flushing toilet. However, in some countries, this share remains comparatively high. In particular, Romania reported figures far above all other Member States, with 21.2 % of the population not having access to basic sanitary facilities in 2020. Relatively high shares were also reported by Lithuania, Bulgaria and Latvia with values between 6.4 % and 7.0 % in the same year. These figures highlight the strong link between access to basic sanitary facilities and poverty, which can be seen across the EU. In 2020, 5.1 % of poor people in the EU lacked access to a bath, shower or toilet in their households, compared with only 0.8 % of those living above the **poverty threshold**.

Connection to secondary waste water treatment is another important facility for enhancing access to sanitation. Connection rates have increased slowly but continuously across the EU, with 81.1 % of the EU population connected in 2020. This is almost 10 percentage points higher than in 2005, when the connection rate was 71.8 %. Between 2015 and 2020, connection rates increased in

81.1 %
of the EU
population
were connected
to at least
secondary
waste water
treatment in
2020

almost all reporting Member States. The lowest-scoring countries were in south-east Europe. It is important to note that connection rates are not expected to reach 100% in most cases because connection costs can be disproportionately high in some areas, in particular for rural areas with a low [population density](#). The Urban Waste Water Treatment Directive only obliges bigger agglomerations to introduce secondary treatment, while requiring smaller agglomerations to apply an appropriate treatment (when waste water is collected) or other alternative solutions to reach the same level of protection for water bodies. However, the Commission's proposal to review the [Urban Waste Water Treatment Directive](#) suggests making this obligation applicable for smaller agglomerations too.

Water quality

Diffuse pollution by agriculture, accidental spillage of harmful substances and discharge of untreated or insufficiently treated domestic and industrial waste water, as well as atmospheric deposition of pollutants such as mercury, can pose a threat to human and environmental health. These pressures, along with changes to the structure and flow of water bodies, pose a barrier to sustainable development. Water quality monitoring distinguishes between different kinds of chemical pollution such as organic pollution by nutrients, pesticides and pathogens. In this report, water quality is monitored through four indicators looking at nutrients in freshwater and at bathing water quality ⁽¹⁾.

Improved waste water treatment has reduced organic pollution in European rivers

Heavy organic pollution, caused by municipal waste water and effluents from industry or livestock, can lead to the deoxygenation of water, killing fish and invertebrates. Thanks to improved waste water collection and treatment, as well as mature treatment, organic pollution in European rivers has been declining, though the trend has slowed in recent years. A proxy for organic water pollution is the amount of oxygen needed

for microbes to digest organic pollution under standard conditions, expressed as biochemical oxygen demand (BOD). BOD values of rivers in Europe range from less than 1 milligram per litre (mg/L) (very clean) to more than 15 mg/L (heavily polluted).

Available data for 18 Member States (see page 128) show an overall decline in BOD in EU rivers, from 3.0 mg/L in 2005 to 2.7 mg/L in 2020. The trend, however, has not been continuous. While BOD levels were showing a downward trend up to 2010, they had climbed back to 3.0 mg/L by 2015 before falling again. Recently, there has been a small increase from 2.6 mg/L in 2019 to 2.7 mg/L in 2020. Overall, BOD levels in EU rivers have fallen by 10.8%

since 2005 and by 12.8% since 2015. The overall decrease in BOD values is mainly linked to a general improvement in waste water collection and treatment throughout Europe.

Between 2015 and 2020, the biochemical oxygen demand in EU rivers fell by 12.8%

Eutrophication is still a major issue for Europe's aquatic environment

An assessment of European waters published by the European Environment Agency (EEA) in 2018 concludes that although nutrient pollution has fallen since the 1990s, it is still the main reason why 28% of EU surface water bodies have not achieved good water quality ⁽²⁾. In some regions, pollution of rivers with nitrate/ammonia (N) and phosphorous (P) is still causing severe eutrophication in coastal waters. Eutrophication can lead to algal blooms and oxygen depletion of surface waters, which in turn can harm fish, invertebrates and whole ecosystems.

The main sources of nutrient inputs are the use of fertilisers and animal waste in agriculture, as well as poorly treated waste water from industry ⁽³⁾. Nitrates (NO₃), among other chemicals, can infiltrate and contaminate groundwater bodies. They are the most common cause of poor

chemical status of groundwater in the EU — 18 % of groundwater bodies by area across 24 Member States are in poor status because of nitrates ⁽⁴⁾. This is particularly problematic because groundwater is an important source of drinking water in Europe.

Data on nitrate concentrations in EU groundwater are available for 18 Member States (see page 129). They show a long-term stagnation of NO₃ concentrations at around 23 mg/L, with a slight downward trend in 2019 and 2020. Due to annual fluctuations in the data, a smoothed four-year average is used to better depict the trend over time. This shows a 3.2 % decrease in the average EU nitrate concentrations between 2015 and 2020. Additionally, between 2016 and 2019, 14.1 % of groundwater stations showed NO₃ concentrations above the threshold considered unfit for drinking, which is set at 50 mg/L by the Nitrates Directive ⁽⁵⁾. The comparatively small changes at European level do not mean that overall groundwater nitrate concentrations remain stable, but rather that some groundwater bodies in Europe are showing an upward trend, while others are showing a downward trend ⁽⁶⁾.

Data on phosphate (PO₄) concentrations in EU rivers are available for 18 Member States (see page 130). They show a marked improvement between 2007 and 2013, after which, however, the trend levelled off and even started increasing again. Thus, while the phosphate concentration of 0.072 mg/L recorded in 2020 is considerably below the values reported in the early 2000s of around 0.087 mg/L, it is 24.1 % higher than in 2015. The overall positive long-term trend is to some extent the result of measures implemented under

Between 2015 and 2020, the four-year average concentration of nitrates in EU groundwater decreased by 3.2 %

Between 2015 and 2020, the concentration of phosphates in EU rivers increased by 24.1 %

the Urban Waste Water Treatment Directive over the past 30 years, especially the introduction of phosphate-free detergents ⁽⁷⁾. The recent turnaround may be related to the slower decline in phosphorus emissions from the agricultural sector and increased phosphorus fertiliser consumption at EU level ⁽⁸⁾.

The share of inland bathing waters with excellent water quality has fallen in recent years

Contamination of water by faecal bacteria continues to pose a risk to human health. This is especially the case when it is found at bathing water sites, where it can cause illness among swimmers. Overall, the share of inland water bathing sites with excellent water quality in the EU increased between 2011 and 2017, followed by a decline up to 2020 and a slight improvement in 2021. The downward trend has been caused by a stagnation in the absolute number of bathing sites recording excellent water quality while at the same time the number of bathing sites included in the assessment has increased. According to the latest European Environment Agency (EEA) data, 78.2 % of inland water bathing sites

showed excellent bathing water quality in 2021, compared with 82.1 % in 2016 and 77.7 % in 2020. The major sources of bathing water pollution are sewage and water draining from farmland. Such pollution increases during heavy rains and floods which wash sewage overflow and polluted drainage water into rivers and seas.

78.2 % of inland water bathing sites in the EU showed excellent bathing water quality in 2021

Water scarcity

SDG 6 also focuses on the sustainable use of freshwater resources and on reducing water stress. The regionalised water exploitation index (WEI+) aims to illustrate the pressure on renewable freshwater resources due to water demand, which is largely affected by population

trends and socio-economic developments, and climate conditions, which control the availability of renewable freshwater resources. Due to a change in the reference database for the WEI+, the data presented in this report are not comparable to those shown in previous editions.

Water stress is low in most EU countries, but shows strong seasonal and local variability

Water stress occurs when water demand exceeds the available water resources at a specific place and time. Water scarcity is generally considered to occur when the ratio of water abstraction to long-term average available water resources exceeds 20 %, while ratios above 40 % indicate severe water scarcity, meaning the use of freshwater resources is unsustainable ⁽⁹⁾. Using a four-year smoothed average shows that the EU's WEI+ decreased by 0.9 index points over the past 15 years, from 5.0 % in 2004 to 4.1 % in 2019. Between 2014 and 2019, however, the WEI+ has stagnated at this level. A look at the annual figures shows that the change in the EU's WEI+ was not constant but

Between 2014 and 2019, the EU's water exploitation index (WEI+) stagnated at 4.1 %

varied both annually and between Member States. Apart from socio-economic developments, the recent stagnation can be attributed to more frequent and severe droughts, which have affected water availability in an increasingly larger area in the EU ⁽¹⁰⁾.

In 2019, Cyprus showed severe water stress with a mean annual WEI+ of 113 %, while Malta showed water stress with a mean annual WEI+ of around 30 %. However, annual national values can mask regional and seasonal water stress, which is in fact common in many European regions ⁽¹¹⁾. In 2019, almost a third (29 %) of the EU territory, excluding Italy, was affected by water scarcity conditions in at least one quarter of the year, with WEI+ values of above 20 % ⁽¹²⁾.

Water scarcity is more common in southern Europe, where about 30 % of the population live in areas with permanent water stress and up to 70 % live in areas with seasonal water stress during summer ⁽¹³⁾ caused mainly by abstractions for agriculture, public water supply and tourism ⁽¹⁴⁾. However, water scarcity also affects river basins in other parts of the EU, particularly in western Europe, where it is caused primarily by high population densities in urban areas, combined with high levels of abstraction for public water supply, energy and industry ⁽¹⁵⁾.

7

Ensure access to affordable, reliable, sustainable and modern energy for all

SDG 7 calls for ensuring universal access to affordable, reliable and sustainable energy. This includes improving energy efficiency, increasing the share of renewables and further diversifying the energy mix while ensuring affordability of energy for citizens.

In everyday life, our well-being and the workings of the economy depend on reliable, affordable and sustainable energy services, such as electricity supply, heating and cooling, and transport services. Monitoring SDG 7 in an EU context involves looking at developments in energy consumption, energy supply and access to affordable energy. As illustrated by the figure on the right, the EU has made slight progress towards this SDG over the past five years. In the area of energy consumption, the EU needs to speed up progress in light of the more ambitious 2030 energy consumption reduction targets agreed in March 2023. In the area of energy supply, the EU has made progress towards the newly agreed 2030 target requiring renewable energy to reach a 42.5% share, although the pace has slowed in recent years. The EU achieved its 2020 target for renewable energy to reach a 20% share and it reduced its import dependency slightly. Access to affordable energy has improved over the past few years. It is important to note that the most

recent data presented in this chapter refer to 2021, so do not yet reflect the recent developments related to the effects of Russia's invasion of Ukraine on energy consumption and supply.

Policy context

The [European Green Deal](#) with its ‘[Delivering on the European Green Deal](#)’ package envisages the decarbonisation of Europe’s energy systems in order to reach climate neutrality by 2050. To reach the [new EU climate target for 2030](#), the Commission proposed an interconnected set of measures in the areas of energy, transport, taxation and climate policies, also called ‘[Fit for 55](#)’. The [Recovery and Resilience Facility](#) supports reforms and investments into sustainable mobility, energy efficiency and renewable energy.

[REPowerEU](#) is a new strategic plan for reducing the EU’s dependence on energy imports, particularly from Russia. In March 2022, the [Communication on security of supply and affordable energy prices](#) outlined immediate measures to prepare for the next two winters, including an obligatory gas storage target. Since then, the EU has agreed emergency [rules on safeguarding gas supply](#), which outline voluntary and mandatory energy consumption reductions, as well as an [emergency regulation](#), which includes joint purchasing of gas, a market correction mechanism for gas trade, market interventions in the electricity sector, and the promotion of solidarity among Member States.

Energy consumption

The amended [Energy Efficiency Directive](#) was introduced to improve energy efficiency by at least 32.5 % by 2030 compared with the 2007 reference year. In July 2021, the Commission [proposed a revision](#), which would implement energy efficiency as a priority across all sectors, increase the ambition of the 2030 target and make it binding for the EU as a whole. [Negotiations](#) among EU co-legislators ended in March 2023 with an agreement to reduce final energy consumption by at least

11.7 % in 2030, compared with the 2030 energy consumption forecasts made in 2020.

Energy supply

The 2018 [Renewable Energy Directive](#) established a binding target for the share of renewable energy sources in final energy consumption to reach at least 32 % by 2030. The Commission [proposed a revision of the Directive](#) in July 2021, including increasing the target to 40 % and strengthening measures for transport, heating and cooling, and a more circular energy system. In May 2022, the [REPowerEU](#) plan proposed to further increase the target to 45 % by 2030. Negotiations among EU co-legislators concluded in March 2023, with an agreement to raise the share of renewable energy in the EU’s overall energy consumption to 42.5 % by 2030, with an additional 2.5 % indicative top-up that would allow it to reach 45 %.

Access to affordable energy

The [European Pillar of Social Rights](#) lists energy among the essential services that everyone should have access to, and the Commission released its first status report in 2023. In April 2022, the Commission established the [Energy Poverty and Vulnerable Consumers Coordination Group](#) to help Member States tackle energy poverty. The [SAFE](#) (Supporting Affordable Energy) measures proposed in October 2022 under the Cohesion Policy will enable Member States to use unspent funds under their 2014–2020 allocation to provide direct support to vulnerable families and small and medium-sized businesses (SMEs) to help them face increased energy costs.

The [EU Energy Poverty Advisory Hub](#) is an initiative that provides a central platform offering energy poverty expertise to local authorities and other stakeholders.

Affordable and clean energy in the EU: Overview and key trends

Energy consumption

Increasing energy efficiency is one of the main pillars for reaching an affordable, reliable, sustainable and modern energy system as envisaged in SDG 7. Efficient energy systems reduce consumption and costs, decrease energy dependencies and diminish the environmental and climate impacts linked to energy supply and use. The EU consequently aims to improve energy efficiency along the whole energy supply chain.

Energy consumption has bounced back after the COVID-19 pandemic significantly reduced consumption in 2020

The EU aims to increase its energy efficiency by at least 32.5 % by 2030, which should be achieved through energy consumption reductions alongside increased economic activity. Because the target was set in relation to business-as-usual projections of energy consumption and economic growth, it was translated into absolute levels of energy consumption for monitoring purposes. This equated to an initial target limiting EU consumption to 1 128 million tonnes of oil equivalent (Mtoe) of primary energy and 846 Mtoe of final energy per year by 2030. However, in spring 2023, an agreement was reached to increase the 2030 target's ambition, to limit the EU's consumption to no more than 993 Mtoe of primary energy and 763 Mtoe of final energy by 2030.

The EU's primary energy consumption has seen a general downward trend since 2006, reaching 1 309.0 Mtoe in 2021, which amounts to a 13.4 % reduction over the past 15 years. In comparison, final energy consumption has fallen to 967.9 Mtoe

or 7.5 % over the same period. The difference in reductions can be mainly traced back to more efficient energy production and the switch to renewable energies (1). Long-term progress on both fronts was due to various factors, including a structural transition towards less energy-intensive industries in many Member States and improvements in end-use efficiency in the residential sector.

The short-term trend has been influenced by a remarkable drop in energy consumption of more than 8 % in 2020 compared with 2019, mainly as a result of measures taken to tackle the COVID-19 pandemic. The economic recovery in 2021 and a return to pre-pandemic mobility patterns has increased energy needs, although consumption has stayed below pre-pandemic levels. Overall, the EU's primary energy consumption fell by 4.0 % between 2016 and 2021, while final consumption decreased by 0.9 % only. Additional improvements in energy efficiency and consumption patterns appear necessary to ensure the EU meets both of its new, more ambitious 2030 energy consumption targets.

EU citizens' energy consumption at home increased slightly

Households account for about a quarter of final energy consumption. At home, people use energy in particular for heating, cooling, cooking, lighting, sanitary purposes and appliances. The level of household energy consumption mainly depends on outdoor temperatures, energy performance of buildings, use and efficiency of electrical appliances, and behaviour and economic status of inhabitants (for example, their desired or affordable level of thermal comfort, frequency

of clothes washing, use of TV-sets, games and lighting preferences).

Household energy consumption has slightly increased since 2016. In 2021, the average household energy consumption was 586 kilograms of oil equivalent (kgoe) per EU inhabitant, which is about 3.9% more than in 2016. The data show some annual variability that depends mainly on weather conditions during winter, as more than 60% of energy is used for heating.

When viewed over the longer term, efficiency improvements, in particular in space heating, seem to have balanced the effect of population growth and increases in the number and size of dwellings. Since 2006, energy consumption per EU inhabitant has fallen by 3.6%, with a slight downward trend in total household energy consumption offsetting a 2.3% or 10.4 million ⁽²⁾ increase in the population over the same period.

The EU has increased its energy productivity

Recent trends in Europe point to a decoupling of economic growth from energy consumption, which is measured here using gross domestic product (GDP) and gross available energy (GAE) respectively. Between 2006 and 2021, GAE fell by 12.4% and thus by a similar amount to primary energy consumption. Over the same period, real GDP grew by 15.4% ⁽³⁾. As a result, energy productivity — which measures GDP per unit of energy input — increased almost continuously, from EUR 6.5 per kgoe in 2006 to EUR 8.5 per kgoe in 2021.

586
kgoe
of final energy
were consumed
by each EU
inhabitant at
home in 2021

Energy supply

To achieve a clean and secure energy system, the EU is aiming to increase the share of renewable energy in gross final energy consumption. In March 2023, the EU co-legislators agreed to increase the ambition of the EU's 2030 target from at least 32% by 2030 to 42.5%, with an additional 2.5% indicative top-up that would allow the EU to reach 45%. Most renewable energy sources are considered to be practically inexhaustible or renewable within a human lifetime. In contrast, fossil energy sources regenerate over millions of years and are the main source of man-made greenhouse gas (GHG) emissions, and therefore contribute significantly to the climate crisis. In addition, fossil fuels such as natural gas and crude oil are mainly imported from outside the EU. This dependence exposes consumers to significant costs and to the risk of supply shortages, as shown by the reduction in natural gas and crude oil deliveries from Russia. The risks increase as dependency on a single country grows. Therefore, the EU is seeking to increase domestic energy production, particularly from renewable energy sources, as well as reduce its energy consumption, and build and update infrastructure to allow clean energy to be distributed across Member States. The EU has also introduced sustainability criteria to address the negative impacts of certain renewable energy sources such as hydropower and biofuels on other SDGs such as health, water and marine and terrestrial ecosystems ⁽⁴⁾.

The share of renewables has kept rising in the EU, but stronger progress appears necessary to meet the 2030 target

Use of renewable energy has grown continuously in the EU, doubling from 10.8% of gross final energy consumption in 2006 to reach 21.8% in 2021. Reductions in investment costs due to economies of scale and greater competition, more efficient technologies, supply chain improvements and renewable energy support schemes have driven this growth ⁽⁵⁾. However, even faster growth is likely to be needed for the EU to meet its newly agreed 42.5% target in 2030.

In 2021, the
EU's energy
productivity
amounted to
EUR 8.5
per kgoe

The share of renewable energy grew in all three of the areas monitored here, namely electricity generation, heating and cooling, and transport. In 2021, the share of renewables in these areas was 37.5 %, 22.9 % and 9.1 %, respectively. However, additional efforts are required across these sectors to scale up the renewable energy transition.

In 2021, the share of renewable energy in gross final energy consumption varied widely across Member States, due to differences in the availability of renewable sources and financial and regulatory support. Sweden had a substantial lead with a share of 62.6 %, followed by Finland and Latvia with shares of 43.1 % and 42.1 %, respectively. These particularly high shares were reached using hydropower and solid biofuels.

Across all Member States, the largest share of renewable energy production in 2021 came from solid biofuels (41.4 %), followed by wind energy (13.2 %) and hydropower (11.9 %). Solid biofuels and wind energy also made the biggest contribution to the absolute increase in renewable energy production between 2016 and 2021. Energy production from heat pumps more than doubled and solar photovoltaic power increased by two-thirds, meaning these two sources saw the largest percentage increase over the period ⁽⁶⁾.

Fossil fuel imports still cover more than half of the EU's energy demand

Despite continuous growth in renewable energy sources over the past decade, fuel imports from non-EU countries remained an important energy source for the EU in 2021, contributing to 55.6 % of gross available energy (GAE) — as measured by net imports (imports minus exports). This is just slightly below the share in 2006, when net imports met 58.3 % of the EU's energy needs. This stagnation can be explained by two opposing developments. On the one hand, the EU reduced its energy consumption and increased its use

of domestic renewables. On the other hand, it reduced its primary production of fossil fuels because of exhausted or uneconomical domestic sources, particularly natural gas ⁽⁷⁾. Therefore, in 2021, net imports were highest for oil and petroleum products (92.0 % imported), followed by natural gas (83.4 % imported) and solid fuels (predominantly coal) (37.4 % imported). Net imports of renewable energy including biofuels accounted for 8.9 % of gross available renewable energy in 2021 and just 1.8 % of total net imports ⁽⁸⁾.

Russia continued to be the main supplier of energy to the EU in 2021, accounting for 44.1 % of gas, 28.4 % of petroleum product and 52.4 % of solid fuel imports from outside the EU. This shows the EU's significant dependence on Russian energy deliveries, which according to [the most recent quarterly data](#) fell significantly in 2022 after Russia cut gas supplies to the EU and the EU accelerated its phase-out of Russian fossil fuels through sanctions on coal and crude oil and by increasing its diversification efforts. By some distance, the next largest sources of gas and petroleum products were European countries outside the EU (mainly Norway and the UK), which supplied 18.0 % of gas and 15.4 % of petroleum imports. The second largest source for solid fuels was North America, which supplied 17.9 % ⁽⁹⁾. All percentages reported here refer to shares of total imports from outside the EU only, so do not account for energy traded between Member States.

In 2021, all Member States were net importers of energy, with 16 importing more than half of their total energy consumption from other countries (EU countries and non-EU countries). Countries with the highest shares of imports in 2021 were the island countries Malta (97.1 %) and Cyprus (89.5 %), along with Luxembourg (92.5 %), which imported almost all of their energy.

**Net imports
amounted to
55.6%**
of the gross
available energy
in the EU in 2021

Access to affordable energy

SDG 7 emphasises the need for affordable energy for reasons of social equality and justice. Principle 20 of the [European Pillar of Social Rights](#) also places energy among the essential services everyone should have access to. The inability to keep the home adequately warm is a survey-based indicator used to monitor access to affordable energy throughout the EU. A lack of access to affordable energy is strongly associated with low levels of income in combination with high expenditure on energy and poor building efficiency standards ⁽¹⁰⁾.

6.9%
of the EU
population
were unable to
keep their home
adequately
warm in 2021

Access to affordable energy has been improving since 2012

The EU has made progress on improving access to affordable energy over the past few years. Between 2012 and 2019, the share of people unable to afford to keep their homes adequately warm fell steadily, from 11.2 % to 6.9 %. In 2020, the share temporarily rose to 7.5 %, only to fall again to 6.9 % in 2021. The data do not yet reflect the

impacts of the recent price spikes following cuts in Russian energy supplies.

People with an income below the [poverty threshold](#) are more likely to report an inability to keep their home adequately warm. In 2021, this was the case for 16.4 % of people from this group, compared with only 4.9 % of people with an income above the poverty threshold.

In 2021, 20 Member States indicated that less than 10 % of their population reported an inability to keep their homes adequately warm. Northern and most western European countries, with particularly cold winters, had the lowest shares of people without affordable access to heating. In contrast, the lack of adequate warmth appeared to be a problem particularly in southern and south-eastern Europe. This distribution can be traced mainly to poor building energy efficiency, including the lack of suitable heating systems and insulation, leading to higher heating costs. In addition, the generally lower income levels in these regions affect housing standards and the ability to pay for fuel. The existence and design of financial interventions by the respective governments might also play an important role in alleviating energy poverty and helping to keep homes adequately warm ⁽¹¹⁾.

Presentation of the main indicators

A variety of energy indicators are used to measure energy consumption at different stages of the supply chain and progress towards the EU energy targets. The following box explains the indicators and the differences between them.

Definitions of energy terms/concepts:

Gross available energy (GAE): represents the total energy demand of a country. It is defined as: **primary production + recovered/recycled products + imports – exports + stock changes.**

Gross inland energy consumption (or gross inland consumption; GIC): represents energy demand including international aviation but excluding **maritime bunkers**. It is defined as: gross available energy – international maritime bunkers.

Total energy supply: represents the total energy delivered and/or consumed in a country excluding deliveries to international aviation and international marine bunkers. It is defined as: gross inland energy consumption – international aviation.

Primary energy consumption (PEC): represents a country's total energy demand including consumption of the energy sector itself, losses during transformation and distribution, and the final consumption by end users. This means it excludes, for example, natural gas used in non-energy products, such as chemicals. It is defined as: gross inland energy consumption – non-energy use of energy carriers.

Primary energy consumption (2020–2030): measures the progress towards the EU's 2020 and 2030 energy efficiency targets. It deviates from primary energy consumption only in that it excludes ambient heat. It is defined as: primary energy consumption – gross inland consumption of ambient heat (heat pumps).

Gross final energy consumption (or gross energy consumption): is the basis for measuring the share of renewable energies according to Directive 2009/28/EC on the promotion of renewable energies. It represents the energy commodities delivered for energy purposes to industry, transport, households, services including public services, agriculture, forestry and fisheries, the consumption of electricity and heat by the energy branch for electricity, heat and transport fuel production, and losses of electricity and heat in distribution and transmission.

Final energy consumption (FEC) (or final consumption – energy use): measures a country's energy use by end users, such as households, industry and transport. It excludes the energy used by the energy sector itself and losses incurred during energy transformation and distribution and any non-energy use of energy carriers. It is defined as: primary energy consumption – consumption by the energy sector – transformation/distribution losses – statistical differences.

Final energy consumption (2020–2030): measures the progress towards the EU's 2020 and 2030 energy efficiency targets. It deviates from final energy consumption by excluding ambient heat and including international aviation and energy consumption of blast furnaces. It is defined as: final energy consumption – final energy consumption of ambient heat (heat pumps) + international aviation + transformation input blast furnaces (all products) – transformation output blast furnaces (all products) + energy sector blast furnaces (all fossil fuels).

8

Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all

SDG 8 recognises the importance of sustained economic growth and high levels of economic productivity for the creation of well-paid quality jobs and calls for opportunities for full employment and decent work for all.

Sustainable economic growth and decent work are vital for the development and prosperity of European countries and the well-being and personal fulfilment of individuals. Monitoring SDG 8 in an EU context involves looking into trends in the areas of sustainable economic growth, employment and decent work. As illustrated by the figure on the right, the EU has made strong progress towards SDG 8 over the assessed five-year period. The EU's economy has grown, which in turn has led to an improvement in the EU's overall employment situation. The EU is thus on track to meet its respective 2030 targets for the overall employment rate and for the share of young people neither in employment nor in education or training. Additionally, working conditions have also improved, with fewer fatal work accidents and fewer people being affected by in-work poverty.

Policy context

Sustainable economic growth

The [Sustainable Europe Investment Plan](#) under the [European Green Deal](#) will mobilise at least EUR 1 trillion in sustainable investments over the next decade.

[NextGenerationEU](#) is a EUR 750 billion temporary recovery instrument to help repair the immediate economic and social damage brought about by the COVID-19 pandemic. The [Recovery and Resilience Facility](#) makes EUR 672.5 billion in loans and grants available to support reforms and investments undertaken by EU countries.

The [8th Environment Action Programme](#) from 2022 aims to decrease the EU's material and consumption footprints and foster a regenerative well-being economy.

The [Competitiveness Strategy beyond 2030](#) presents a coordinated EU framework to spur competitiveness and prosperity in the longer term.

Employment

The [European Pillar of Social Rights Action Plan](#) aims to increase the employment rate of people aged 20 to 64 to at least 78% and to reduce the share of young people aged 15 to 29 neither in employment nor in education or training to less than 9% by 2030.

The [Council Decision on guidelines for the employment policies of the Member States](#) updated in 2022 puts a strong focus on the post-COVID-19 environment, socially fair green transition and measures in response to Russia's aggression against Ukraine.

The [Council Recommendation on access to social protection for workers and the self-employed](#) from 2019 extends the coverage

of social protection systems across the EU. The [Directive for Work-Life Balance](#) aims to improve families' access to leave and flexible work arrangements to facilitate women's participation in the labour market.

The [Council Recommendation on the integration of the long-term unemployed into the labour market](#) aims to help long-term unemployed people re-enter the labour market.

The [European Social Fund](#) and the [Youth Employment Initiative](#) support quality employment, further education, quality traineeships and apprenticeships. The [European Social Fund Plus](#) fosters youth employment through funds allocation.

Decent work

The [Communication on Decent Work Worldwide](#) reaffirmed the EU's commitment to championing decent work both at home and around the world. The [Directive on adequate minimum wages in the European Union](#) aims to ensure that EU workers earn minimum wages that allow a decent living. The [Directive on transparent and predictable working conditions in the EU](#) sets new minimum standards on working conditions.

The [EU strategic framework on health and safety at work 2021–2027](#) sets out key priorities for improving workers' health and safety. The proposal for an amendment of the [Asbestos at work directive](#) will provide additional protection to workers.

The [Communication](#) and the [proposal for a Council Recommendation](#) on strengthening social dialogue in the EU promote concrete actions at national and EU level.

Decent work and economic growth in the EU: overview and key trends

Sustainable economic growth

While economic growth is an important driver of prosperity and society's well-being, it can also harm the environment it depends on. To ensure the well-being of future generations, the EU has adopted a new growth strategy, the [European Green Deal](#), aimed at transforming the Union into a modern, resource-efficient, fair and competitive economy. The indicators selected to monitor this objective show that over the assessed five-year period, Europeans have generally enjoyed continuous economic growth while their material footprint has decreased — although the latter is likely to be a temporary effect of the COVID-19 pandemic.

Real GDP per capita grew by 3.3 % in 2022

Citizens' living standards depend on the performance of the EU economy, which can be measured using several indicators. One of these is growth in [gross domestic product \(GDP\)](#). Although GDP is not a measure of welfare, it gives an indication of an economy's potential to satisfy people's needs and its capacity to create jobs. It can also be used to monitor economic development.

Real GDP per capita (GDP adjusted for inflation) in the EU saw strong and continuous growth of 2.0 % per year on average between 2014 and 2019. In 2020, the economy was hit by the COVID-19 pandemic, resulting in a 5.7 % contraction of real GDP compared with 2019. Nevertheless, the economy rebounded from the recession in the following years. In 2022, real GDP per capita grew by 3.3 % compared with the previous year and

reached EUR 28 820 — this is a record high despite the economic reverberations of Russia's ongoing war of aggression against Ukraine. This growth was mostly driven by a spending spree that came with an easing of COVID-19 containment measures ⁽¹⁾. In 2023 and 2024, GDP in the EU is projected to expand by 0.8 % and 1.6 %, respectively ⁽²⁾.

Investment is another indicator of economic growth as it enhances an economy's productive capacity. In 2022, the total investment share of GDP in the EU reached 23.2 % — the highest level recorded since 2008. [Businesses](#) were the biggest investors in 2022, with an investment share in GDP of 14.0 %, followed by households with 6.0 % and governments with 3.2 %. The investment share of households has been slowly growing since 2016 but still remains below the levels before the 2008 financial crisis. This is most likely because [household investment](#) consists mainly of the purchase of dwellings. Government investment has followed a counter-cyclical pattern, increasing during both the financial crisis of 2008 and the COVID-19 crisis in 2020.

EU's material footprint decreased in 2020 as a result of the pandemic

Economic growth helps to satisfy peoples' material needs, which, in turn, can put pressure on the environment. The EU, therefore, aims to lower this pressure by reducing the Union's material footprint. The EU's material footprint, also referred to as raw material consumption (RMC), shows the amount of material extracted from nature, both inside and outside the EU, to manufacture or provide the goods and services consumed by EU inhabitants. In other words, it refers to the

resources needed to sustain the EU's economic and social activities.

The EU's material footprint had been growing between 2000 and 2007, before it was halted by the economic crisis of 2008. As the EU's economy recovered, consumption had started to rise again, increasing by 4.3 % between 2014 and 2019. In 2020, EU inhabitants consumed 6.11 billion tonnes of raw material, which was 5.6 % less than the previous year and the lowest value observed since 2000. This fall is likely to be influenced by the economic slowdown due to the COVID-19 pandemic. Despite an overall decrease in RMC since 2000, the EU's total material footprint is above the global average and exceeds sustainable levels of resource extraction. This means that Earth's capacity to provide resources would be exceeded if all countries in the world were to consume resources at the same rate as the EU ⁽³⁾. Discounting the temporary dip in 2020, RMC had been increasing over the past few years, which means the EU is not on track to significantly reduce its material footprint, as envisioned by the European Green Deal and the 8th Environmental Action Programme. For more information on the EU's material footprint, see the chapter on SDG 12 'Responsible consumption and production' on page 219.

6.11
billion tonnes
of globally
extracted raw
material were
consumed in
the EU in 2020

Employment

Decent employment for all — including women, people with disabilities, young people, older people, those with migrants backgrounds and other disadvantaged groups — is a cornerstone of socio-economic development. Apart from generating the resources needed for decent living standards and achieving life goals, work provides opportunities for meaningful engagement in society, which in turn promotes a sense of self-worth, purpose and social inclusion. Higher employment rates are a key condition for making

societies more inclusive by reducing poverty and inequality in and between regions and social groups. The [European Pillar of Social Rights Action Plan](#) sets a target for at least 78 % of the population aged 20 to 64 to be in employment by 2030. It also envisions the complementary ambition of at least halving the gender employment gap and decreasing the rate of young people aged 15 to 29 who are neither in employment nor in education or training (NEETs) to 9%.

The employment rate in the EU reached a historic high in 2022

Before the COVID-19 pandemic, the EU [employment rate](#) exhibited an upward trend, reaching 72.7 % in 2019. In 2020, the rate fell by one percentage point as a result of the socio-economic impacts of the pandemic, but has started increasing again. Despite the uncertain and challenging environment caused by Russia's war of aggression against Ukraine, the employment rate in the EU reached a record high of 74.6 % in 2022. However, the slowing of economic activity is expected to weigh on the pace of the employment growth in 2023 and 2024 ⁽⁴⁾. Nevertheless, if the employment growth observed since 2017 continues, the EU will be well placed to reach its target of 78 % by 2030.

74.6 %
of 20- to
64-year-olds
were employed
in the EU in
2022

An analysis by degree of urbanisation reveals that employment rates in cities, towns and suburbs and rural areas were all affected by the COVID-19 crisis, decreasing by between 0.8 and 1.0 percentage points from 2019 to 2020. By 2022, the employment rates had recovered, reaching 74.9 % in cities, 74.2 % in towns and suburbs and 74.8 % in rural areas. The employment gap between cities and rural areas has thus narrowed to 0.1 percentage points in 2022, after amounting to 0.3 to 0.5 percentage points between 2017 and 2021 ⁽⁵⁾.

Unemployment and long-term unemployment reached all-time low in 2022

The EU's unemployment situation has been steadily improving since 2014, disregarding a temporarily COVID-19-related drop in 2020. Between 2014 and 2022, the EU's unemployment rate for the age group 15 to 74 decreased by 4.8 percentage points, affecting 6.2 % of the population in the **labour force** in 2022 — the lowest value recorded since 2009 ⁽⁶⁾. Over the past years, city dwellers have been more affected by unemployment than those living in rural areas. In 2022, the unemployment rate in cities was 6.8 % compared with 5.3 % for rural areas ⁽⁷⁾.

Long-term unemployment usually follows the trends in unemployment, but with a delay, meaning that the effects of the COVID-19 pandemic are only visible in 2021 data. Being unemployed for a year or more can have long-lasting negative implications for individuals and society by reducing employability prospects, contributing to human capital depreciation, endangering social cohesion and increasing the risk of poverty and social exclusion. Beyond material living standards, it can also lead to a deterioration of individual skills and health status, thus hindering future employability, productivity and earnings.

As a result of the COVID-19 pandemic, long-term unemployment in the EU increased by 0.3 percentage points from 2020 to 2021, affecting 2.8 % of the labour force in 2021. However, already in 2022 the rate returned to a decreasing path and reached the lowest value on record at 2.4 %. The proportion of long-term unemployment in total unemployment had been decreasing between 2015 and 2020, before this trend was halted due to the effects of the pandemic. In 2022, the share of long-term unemployment in total unemployment

was 38.5 %, 4.6 percentage points above the level observed in 2020 ⁽⁸⁾.

The labour market situation of young people is improving

The economic growth observed over the past few years has also helped to improve the labour market situation of younger people, with the employment rate of 20- to 24-year-olds growing steadily between 2014 and 2019. Nevertheless, they were hit harder by the COVID-19 crisis than older age groups. This is because young people are more likely to be employed on temporary and other atypical contracts (such as part-time, on-call or zero-hour contracts). However, already by 2022, the youth employment rate (20-24-year-olds) had recovered and reached 53.3 %. While this is the highest level recorded, it is still lower than for other age groups ⁽⁹⁾. This overall low employment rate of people aged 20 to 24 can be explained by the fact that many people at this age are in education and thus not part of the labour force. In addition, youth unemployment was significantly higher than for older age groups. Despite a strong 10.5 percentage point decrease in youth unemployment since 2013, 12.9 % of 20- to 24-year-olds were unemployed in 2022 ⁽¹⁰⁾.

Young people not engaged in employment nor in education and training (NEET) are among the most vulnerable groups in the labour market. Over the long term they may fail to gain new skills and suffer from erosion of competences, which in turn might lead to a higher risk of labour market and social exclusion. To improve the labour market situation of young people, the EU set a complementary target of decreasing the NEET rate to 9 % by 2030.

Between 2013 and 2019, the NEET rate for 15- to 29-year-olds in the EU improved from 16.4 % to 12.8 %. Despite a COVID-19 related increase in

2020, already by 2022 the NEET rate had dropped to 11.7%, which was the lowest value recorded. If this positive trend continues, the EU is well placed to reach its NEET rate target of 9% by 2030. Since 2009, the NEET rate in rural areas and towns and suburbs had been higher than in cities and reached 12.2% in towns and suburbs and 12.6% in rural areas in 2022, compared with a rate of 10.9% in cities ⁽¹¹⁾.

Women's participation in the labour market is growing, but gender differences persist

The employment rate of women in the EU has been increasing since 2009. After a dip caused by the COVID-19 pandemic, it reached a new high of 69.3% in 2022. The [gender employment gap](#), however, continues to persist, despite narrowing by 2.7 percentage points since 2009. In 2022, it amounted to 10.7 percentage points, despite women becoming increasingly well-qualified and even outperforming men in terms of educational attainment (see the chapter on SDG 5 'Gender equality' on page 103).

Inflexible work-life-balance options and underdeveloped care services — both for childcare and long-term care of a family member — are major impediments to women remaining in or returning to work. Caring responsibilities, which include care for children, care for adults with disabilities, and other family or personal responsibilities, are more often performed by women, contributing to the gender employment gap. In the EU, 1.5% of women aged 20 to 64 were outside the labour force because they were caring for children or incapacitated adults, compared with only 0.3% of men in 2022. Caring responsibilities are also the main reason why women are opting for part-time employment ⁽¹²⁾. As a result, women were overrepresented in part-time employment, with

1.5 %
of women in the EU were outside of the labour force because of caring responsibilities in 2022

27.8% of employed women working part-time in 2022, compared with 7.6% of employed men ⁽¹³⁾.

Interestingly, the share of women who indicated caring responsibilities as the main reason for part-time employment in 2022 varied widely across the EU Member States, from 2.5% in Denmark to 45.4% in the Netherlands ⁽¹⁴⁾. Similarly, the share of women working part-time varied significantly. While only 1.7% of women in Bulgaria and 2.7% in Romania performed part-time work, this was the case for 60.6% of women in the Netherlands and 51.0% in Austria in 2022 ⁽¹⁵⁾.

Employment opportunities are lower for people with disabilities

People with disabilities are those who have a basic activity difficulty (such as seeing, hearing, walking or communicating) and/or a work limitation caused by a longstanding health condition and/or a basic activity difficulty ⁽¹⁶⁾. Disabilities impact people's lives in many areas, including participation in the labour market. In 2021, the employment rate of people with disabilities at the EU level was 23.1 percentage points lower compared with people without disabilities. For women with disabilities, this gap was 20.4 percentage points, while for men with disabilities it was 25.1 percentage points. The degree of disability is also an important factor affecting the employment rate. At the EU level, the employment rate for people with a severe disability was 42.8 percentage points lower than for people without a disability, while for people with a moderate disability the gap was 16.2 percentage points in 2021 ⁽¹⁷⁾.

Decent work

For a society's sustainable economic development and well-being it is crucial that economic growth generates not just any kind of job but 'decent' jobs. This means that work should deliver fair income, workplace security and social protection for families, better prospects for personal development and social integration and equality of opportunity ⁽¹⁸⁾.

Over the past few years, work in the EU has become safer and more economically secure

A prerequisite for decent work is a safe and healthy working environment, without non-fatal and **fatal accidents**, where risks of work-related hazardous events or exposures are minimised. Over the past few decades, the EU and its Member States have put considerable effort into ensuring at least minimum standards in occupational health and safety at work. After almost a decade of steady decline, the rate of fatal incidents at work slightly increased in 2020, amounting to 1.8 fatalities per 100 000 employed persons, with the mining and quarrying and construction sectors particularly prone to fatal accidents ⁽¹⁹⁾. One of the reasons behind this increase might be the inclusion of a new category to the definition of an accident at work — COVID-19 of occupational origin — which some countries have already added to their statistics ⁽²⁰⁾. Although the incidence rate increased in 2020, the absolute number of fatal accidents decreased by 1.5 % compared with the previous year. Thus, the increase in the incidence rate may also be attributed to the fact that during the pandemic in 2020, the number of employed people fell by more than the number of fatal accidents did ⁽²¹⁾.

While there has been a significant decrease since 2010, a noticeable gender difference persists: in 2020, the incidence rate for women was only 0.3 per 100 000 persons, compared with 3.1 for men. This gender gap is due to the fact that activities

with the highest incidence rates are mostly male-dominated ⁽²²⁾.

Besides safety at work, fair income and social protection are also important components of decent work. Poverty is often associated with the absence of a paid occupation but low wages can also push some workers below the poverty line. People working part-time or on temporary contracts, low-skilled workers and non-EU born workers are especially affected by in-work poverty. In the EU, the share of the so-called 'working poor' (aged 18 and over) decreased between 2016 and 2020, from 9.8 % to 8.8 %. In 2021, the in-work at-risk-of-poverty rate remained rather stable, at 8.9 % of employed people. For more information on in-work poverty, see the chapter on SDG 1 'No poverty' on page 39.

While a fixed-term, part-time contract or platform work may provide greater flexibility for both employers and workers, it is not always a personal choice for an employee and can thus significantly influence their well-being. In 2022, 4.3 % of European employees aged 20 to 64 were involuntarily working on temporary contracts, corresponding to 33.0 % of all temporary employees. This share has decreased significantly over the past few years ⁽²³⁾. The indicator on labour transitions from temporary to permanent contracts also shows that the share of such transitions has increased since 2015, reaching 27.1 % in 2020 (based on a three-year average) ⁽²⁴⁾. Similar to involuntary temporary employment, the share of involuntary part-time employment in total employment in the EU also decreased, from 5.3 % in 2017 to 3.6 % in 2022 ⁽²⁵⁾.

9

Build resilient infrastructure, promote inclusive and sustainable industrialisation and foster innovation

SDG 9 calls for building resilient and sustainable infrastructure and promotes inclusive and sustainable industrialisation. It also recognises the importance of research and innovation for finding solutions to social, economic and environmental challenges.

Research and development (R&D), innovations, sustainable industries and infrastructures are key to achieving the SDGs. Monitoring SDG 9 in an EU context focuses on elements such as R&D intensity and personnel, patent applications, the air emissions intensity of industry, and modal splits in passenger and freight transport. Over the five-year period assessed in this report, the EU has experienced strong progress in many of these indicators. However, there have also been recent unfavourable trends, especially regarding the use of environmentally friendly modes in freight and passenger transport.

Policy context

R&D and innovation

The [new European Research Area \(ERA\)](#) aims to build a single, borderless area for research, innovation and technology by prioritising investments and reforms, improving access to excellence, translating research and innovation results into the economy and strengthening the mobility of researchers and knowledge through greater cooperation. The Council [Recommendation on a Pact for Research and Innovation in Europe](#) re-affirmed the EU's long-standing objective of increasing its R&D intensity to 3 % of GDP and outlines the long-term vision for the ERA. The [ERA Policy Agenda 2022–24](#) translates the vision into 20 tangible actions. The EU research and innovation programme [Horizon Europe](#) supports researchers and innovators to drive the systemic changes needed to ensure a green, healthy and resilient Europe.

The [European Education Area \(EEA\)](#) is an initiative that enables all young people to benefit from the best education and training and to find employment across Europe. The [European Education Area strategic framework](#) promotes collaboration between EU Member States and key stakeholders and sets the target that by 2030 at least 45 % of 25–34-year-olds in the EU should have completed tertiary education.

The [New European Innovation Agenda](#) (2022) aims to position Europe at the forefront of the new wave of deep tech innovation and start-ups.

The [Recovery and Resilience Facility](#) is a temporary instrument that supports reforms and investments to promote smart, sustainable and inclusive growth, entrepreneurship, competitiveness,

industrialisation and reindustrialisation, improve the business environment, foster research, development and innovation, and support SMEs.

Sustainable industry

The EU's updated [New Industrial Strategy for Europe](#) (2021) aims to support industry to shift towards climate neutrality and to build a more circular economy.

The [EU Bioeconomy Strategy](#) (2018) supports the greening of EU industry, materials and products within planetary boundaries.

The [Green Deal Industrial Plan](#) (2023) seeks to enhance the competitiveness of Europe's net-zero industry and support the fast transition to climate neutrality.

Sustainable infrastructure

The [Sustainable and Smart Mobility Strategy](#) sets various milestones for smart and sustainable transport modes to reach the climate targets of the [European Green Deal](#).

The [Trans-European Transport Network \(TEN-T\)](#) policy aims to implement and develop an effective, EU-wide and multimodal network of roads, railway lines, inland waterways, ports, airports and rail-road terminals. The [Action Plan to boost long-distance and cross-border passenger rail services](#) and the proposed [revision of the TEN-T Regulation](#) aim to contribute to more attractive cross-border options with rail transport.

The [2030 Digital Compass](#) presents a vision for Europe's digital transformation and sets the target that all households should be covered by a gigabit network by 2030.

Industry, innovation and infrastructure in the EU: overview and key trends

R&D and innovation

R&D expenditure is a key enabling factor for smart, sustainable and inclusive growth. Introducing new ideas to the market promotes job creation, labour productivity and efficient use of resources. Highly skilled human resources are imperative for keeping the EU's research and innovation capacity and competitiveness up to date and for supporting the digital and green transitions. Innovative products and services, often as a result of R&D activities, contribute to smart growth and sustainable industrialisation. R&D and innovation are also essential for finding solutions to societal and environmental challenges such as **climate change** and clean energy, public security or health protection and promotion.

EU expenditure on R&D has shown only modest growth

The EU economy is facing increasing global competition and can only remain competitive with other countries and regions in the world by strengthening its scientific and technological base. Therefore, one of the key aims of EU policies over recent decades has been to encourage greater investment in R&D. This is monitored here by looking at gross domestic expenditure on R&D in relation to GDP, referred to as **R&D intensity**. R&D intensity thus reflects both growth in spending on R&D and growth in GDP.

Despite the EU's long-standing 3 % target, the EU's R&D intensity has grown only modestly over the past 20 years. After prolonged stagnation between 2000 and 2007, the EU's R&D intensity has increased slowly, reaching 2.30 % in 2020. Most recently however, the R&D intensity has declined

again, to 2.26 % in 2021. This corresponded to an R&D expenditure of about EUR 328 billion. In absolute terms, expenditure in 2021 was therefore higher than in 2020 (EUR 310 billion) and 2011 (EUR 228 billion) ⁽¹⁾. With a gap of 0.74 percentage points, the EU remains at some distance from its ambition of raising R&D intensity to 3 % by 2030.

Private expenditure accounts for two-thirds of total R&D expenditure

An analysis of gross domestic expenditure on R&D by sector of performance shows that the two biggest spenders in 2021 remained the **business enterprise sector** (66.0 % of total R&D expenditure) and the **higher education sector** (21.6 %). The share of the **government sector** was 11.8 %, while the **private non-profit sector** accounted for less than 1 % of total R&D expenditure ⁽²⁾.

The business enterprise sector accounts for the lion's share of total R&D expenditure and has increased its R&D intensity by 0.4 percentage points over the past 15 years, from 1.13 % of GDP in 2005 to 1.49 % in 2021. Simultaneously the higher education sector increased its R&D intensity from 0.39 % (2005) to 0.49 % of GDP in 2021. In contrast, the R&D intensities of the government and private non-profit sectors have more or less stagnated at lower levels.

The number of patent applications to the European Patent Office has grown

Patent applications provide a valuable measure of the creative and innovative capacity of countries, regions and companies and of the economic exploitation of research results. In 2021, 67 500

2.26 %
of GDP was
spent on R&D in
the EU in 2021

67 500
patent
applications
from within
the EU were
submitted to
the European
Patent Office in
2022

patent applications from within the EU were submitted to the European Patent Office. This figure was reached after an almost continuous period of growth since 2007, when 57 255 applications were submitted. The only year to record a strong year-on-year drop in applications was 2009 as a result of the economic crisis ⁽³⁾.

The availability of human capital for a knowledge-based society is growing, but gender disparities remain

The growing knowledge orientation of the EU's economy and society, together with developments in the labour market and demographic trends, make human capital increasingly important. Achieving the SDGs will require ambitious investments in research and development (R&D) and significant innovation, including further investment in skills development and in lifelong learning ⁽⁴⁾.

R&D personnel consists of researchers engaged directly in R&D as well as those persons providing direct services for the R&D activities (such as R&D managers, administrators, technicians and clerical staff) ⁽⁵⁾. The share of R&D personnel in the labour force has increased steadily since 2006, from 0.97 % to 1.50 % in 2021 (full-time equivalent). This trend was mainly driven by the business enterprise sector, which employed about 60 % of the R&D workforce in 2021.

1.50 %
of the
economically
active
population in
the EU worked
in R&D in 2021

An analysis by sex, however, reveals that women remain considerably underrepresented among researchers based on head count in the EU, accounting for only 32.9 % in 2019. There has been no considerable progress since 2005, when the share stood at 30.2 %. This underrepresentation is particularly strong in the business enterprise sector, where women only made up 21.3 % of researchers in 2019. In contrast, women accounted for more than 40 % of researchers in the other

three sectors (government, higher education and non-profit sector), with the private non-profit sector being the closest to achieving parity at 48.4 % in 2019. Compared with the other sectors, the higher education sector recorded the largest increase in female researchers: between 2005 and 2019, it increased by 6.5 percentage points, from 36.5 % to 43.0 % ⁽⁶⁾.

Data on tertiary educational attainment show a general long-term increase in the EU population's skill levels. Between 2007 and 2022, the share of 25- to 34-year olds with a university degree or similar increased from 28.9 % to 42.0 %. The EU is therefore well on track to reaching its target of raising this share to at least 45 % by 2030, as set out in the [Council Resolution](#) from 2021 on the [European Education Area](#).

However, differences between the sexes remain considerable, and when compared with the situation for R&D personnel, the gender imbalance is reversed. While 47.6 % of women aged 25 to 34 years had accomplished tertiary education in 2022, only 36.5 % of men in this age group had done so. This gender gap has been widening almost continuously since 2007. For further details on tertiary education and the gender gap, see the chapters on SDG 4 'Quality education' on page 87 and SDG 5 'Gender equality' on page 103.

Sustainable industry

Mobilising industry for a clean and circular economy is one of the key priorities of the [European Green Deal](#), which seeks to support and accelerate the EU's industry transition to a sustainable model of inclusive growth. This requires a massive reduction in harmful air emissions emitted through industrial production alongside increased use of greener products and services.

The air emissions intensity of EU industry has improved in recent years

Industry is vital for Europe's prosperity and future development. The EU industrial sector accounts for more than 20 % of the EU economy and employs about 35 million people ⁽⁷⁾. However, industry is also a source of many environmental pressures such as material consumption and the emission of greenhouse gases and other air pollutants. This analysis focuses on air pollutants emitted by industry, using particulate matter emissions from manufacturing as a proxy. For an analysis of greenhouse gas emissions from industry, see the chapter on SDG 13 'Climate action' on page 235.

Poor air quality causes premature deaths, impacts quality of life and damages ecosystems ⁽⁸⁾.

Particulate matter, especially fine particulate matter (PM_{2.5}), is one of the most harmful components of air pollution for human health ⁽⁹⁾. Exposure to air pollution by PM_{2.5} caused 237 810 premature deaths in the EU in 2020 (see chapters on SDG 3 'Good health and well-being' on page 69 and on SDG 11 'Sustainable cities' on page 203). In 2020, the EU's manufacturing sector was responsible for about a fifth (21.7 %) of total PM_{2.5} emissions. In comparison, in the same year, about a third (33.0 %) of total PM_{2.5} emissions could be attributed to transportation and storage, and almost a quarter (24.2 %) to agriculture, forestry and fishing ⁽¹⁰⁾.

Data on emissions intensity monitor a sector's air emissions relative to its economic output in terms of **gross value added (GVA)**. Between 2008 and 2020, the air emissions intensity of fine particulate matter (PM_{2.5}) of the EU's manufacturing sector dropped by 36.4 %, from 0.11 grams per euro to 0.07 grams per euro. This improvement is a result of the sector's PM_{2.5} emissions falling by 30.3 % between 2008 and 2020 while its GVA grew almost continuously until the onset of the

**12.5 %
improvement
in the
manufacturing
sector's
emissions
intensity of
fine particulate
matter between
2015 and 2020**

COVID-19 pandemic. In 2019 — the year before the pandemic — the sector's GVA was 13.5 % higher than in 2008. In 2020, GVA was still higher than in 2008, albeit only by 5.3 %. From 2019 to 2020, the sector thus experienced a stronger fall in its GVA (by 7.2 %) than in its PM_{2.5} emissions (by 5.4 %).

Between 2015 and 2020, PM_{2.5} emissions from manufacturing decreased by 6.6 %, alongside a 1.9 % increase in the sector's GVA ⁽¹¹⁾. This resulted in a 12.5 % improvement in the sector's emissions intensity over this most recent five-year period. The manufacturing sector's emissions intensity for the broader group of fine and coarse particulate matter (PM₁₀) experienced a similar improvement, decreasing by 33.3 % between 2008 and 2020 and by 9.1 % between 2015 and 2020.

Gross value added of environmental goods and services has grown strongly

The EU's updated **New Industrial Strategy for Europe** strives for a greener industry. Products and services that, for instance, prevent or limit environmental pollution, repair and correct resource depletion or protect biodiversity may contribute to a so-called green economy. These kinds of environmental goods and services (EGSS) are gaining in importance. In 2020, they accounted for a gross value added of EUR 300.1 billion. This is a 68.6 % increase compared with 2005, when the EU's GVA of environmental goods and services amounted to EUR 178.0 billion. In relation to the whole economy, the environmental goods and services sector grew from 1.7 % of GDP in 2005 to 2.5 % in 2020. This indicates the sector grew — in gross value added terms — disproportionately faster than other economic sectors. Notably, the sector's GVA continued to grow in 2020 (by 1.9 %) when the EU's GDP fell by 5.6 % as a result of the COVID-19 pandemic.

**300.1
billion EUR
of gross value
added were
generated
by the EU's
environmental
goods and
services sector
in 2020**

Employment (in full-time equivalent) in the sector has also increased since 2005, by 47.5 %. In 2020, the sector employed slightly more than 5 million people in the EU ⁽¹²⁾. The development is related to multiple factors, which, among other things, include growth in private investments in environmental goods and services, encouraged by increasing government interventions in this area ⁽¹³⁾.

Sustainable infrastructure

The [European Green Deal](#) aims to transform the EU into a fair and prosperous society, with a modern, resource-efficient and competitive economy. To achieve this vision, the EU needs to address the twin challenge of the green and the digital transition. In this context, the Green Deal calls for an acceleration in the shift to sustainable and smart mobility as well as for investment in digitalisation to support the green transition. Multimodal and energy efficient freight transport as well as automated and connected multimodal mobility will consequently need to play an increasing role, together with smart traffic management systems enabled by digitalisation.

Use of public transport dropped considerably during the pandemic

Well-functioning and efficient transport and mobility systems are key elements for a competitive economy. Growth in transport activities puts increasing pressure on natural resources and on societies. Emissions of greenhouse gases, air pollutants and noise from transport affect the climate, the environment and human health. As the transport sector is responsible for nearly one-quarter of [greenhouse gas \(GHG\)](#) emissions in the EU (see the chapter on SDG 13 'Climate action' on page 235), sustainable transport is an essential ingredient in sustainable development strategies. Rethinking future mobility includes optimising the use of all means of transport, promoting car sharing and the integration between different modes of collective transport such as trains and buses.

In 2020 the modal share of buses and trains in [inland passenger transport](#) in the EU fell

significantly compared with previous years ⁽¹⁴⁾. While their share in terms of passenger-km has stagnated between 16.9 % and 18.0 % since 2000, and accounted for 17.5 % in 2019, it dropped to 12.8 % in 2020. This corresponds to a 4.7 percentage point decrease within one year. Conversely, the share of passenger-km covered by cars — which remain by far the dominant mode for inland passenger transport — increased to 87.2 % in 2020 ⁽¹⁵⁾.

This drastic development can be essentially attributed to the effects of the COVID-19 pandemic. A [study published by the European Parliament](#) shows that measures such as restrictions on domestic and international travels, teleworking policies as well as changed mobility habits as a consequence of the pandemic led to a significant decline in public transport use in 2020. According to an [EU-wide survey on passenger mobility](#) carried out in 2021, 64 % of the respondents reported that their travel behaviour was impacted by the COVID-19 pandemic.

12.8 %
of passenger-km in the EU were covered by buses and trains in 2020

The EU's freight transport system still relies on road transport

Despite the EU policy objective of shifting freight from road to rail and inland waterways, road continues to have by far the largest share in EU freight transport among the three inland transport modes analysed in this report (road, rail and inland waterways). Since 2012, the share of rail and inland waterways in total freight transport in the EU has declined almost continuously. It accounted for 22.7 % in 2021, which corresponds to a 3.8 percentage point decrease compared with the peak of 26.5 % in 2012.

22.7 %
of freight tonne-km in the EU was carried out via rail and inland waterways in 2021

Considerable differences do exist at country level though. In 2021, three countries (Lithuania, Latvia and Romania) had higher shares for rail and inland waterways than for road in inland freight transport. Particularly high shares of rail transport were reported from the Baltic countries Lithuania (62.5%), Latvia (53.4%) and Estonia (40.1%). In the Netherlands, freight transport via inland waterways still plays an important role, with a modal split of 41.9% in 2021.

Considerable progress has been made in rolling out fixed very high capacity network connections across the EU

Digital connections are crucial for today's economies and societies. Instant communication between individuals, bank transfers, office work, public dissemination of information, or data analysis are only some of the activities that depend on the internet. Especially in rural and remote areas, fast internet connection can significantly improve access to various services such as health care and education. Regions

70.2%
of EU
households
had high-
speed internet
coverage in
2021

without fast internet connections have serious social and economic disadvantages in a digitalised world. The [2030 Digital Compass](#) thus proposed the target that by 2030 all European households should be covered by a gigabit network, with all populated areas covered by 5G.

Data collected by the European Commission services for the [key dimensions of the European information society](#) ⁽¹⁶⁾ show that the uptake of fixed very high capacity network (VHCN) connectivity — referring to fibre connections or other networks offering similar bandwidth ⁽¹⁷⁾ — has improved considerably in the EU over the past few years. While only 25.2% of EU households had access to such connectivity in 2016, this share has risen considerably, reaching 70.2% of households in 2021. If VHCN roll-out continues at this pace, the EU will reach 100% coverage well ahead of 2030. VHCN connectivity has also improved in rural areas ⁽¹⁸⁾. Between 2016 and 2021, the share of rural households with fixed VHCN connection increased from 7.7% to 37.1% across the EU. Despite this positive development, VHCN connectivity in rural areas remains at some distance from the 2030 target. In addition, basic digital skills for all citizens (see the chapter on SDG 4 'Quality education' on page 87) are a general prerequisite for ensuring they benefit from digital developments ⁽¹⁹⁾.

10

Reduce inequality within and among countries

SDG 10 addresses inequalities within and among countries. It calls for nations to reduce inequalities in income as well as those based on age, sex, disability, race, ethnicity, origin, religion, or economic or other status within a country. The goal also addresses inequalities among countries and calls for support for safe migration and mobility of people.

It is widely agreed that economic prosperity alone will not achieve social progress. High levels of inequality risk leaving much human potential unrealised, damage social cohesion, hinder economic activity and undermine democratic participation. Leaving no one behind is thus a crucial part of achieving the SDGs. Monitoring SDG 10 in an EU context thus focuses on inequalities within countries, inequalities between countries, and migration and social inclusion. Over the five-year period assessed, the EU has made moderate progress towards addressing income inequalities within countries, even though the impacts of the COVID-19 pandemic may have slightly widened the income gap between rich and poor people in 2021. The trends in economic disparities between EU countries show a long-term convergence of Member States in terms of GDP and income. The picture remains less clear for migration and social inclusion of people with a migrant background. Despite progress in certain areas, the EU still faces challenges in

eliminating differences in social and labour market inclusion between home-country nationals and non-EU citizens.

Policy context

Inequalities within countries

The [European Pillar of Social Rights](#) sets out 20 key principles to support fair and well-functioning labour markets and welfare systems and to tackle inequalities. It serves as a 'social rulebook' that ensures solidarity between generations and creates opportunities for all.

The [Just Transition Mechanism](#) supports those who will be most affected by the transition to a climate-neutral society. The [Council Recommendation on ensuring a fair transition towards climate neutrality](#) provides guidance for addressing the relevant employment and social aspects linked to the green transition. The [Social Climate Fund](#) will help vulnerable households, micro-enterprises and transport users to cope with the price impacts of an emissions trading system on the road transport and building sectors.

The [Fund for European Aid to the Most Deprived](#) supports the most vulnerable in society by providing them with basic material assistance and social assistance.

The [Communication on better assessing the distributional impact of Member States' policies](#) calls for the impact of planned measures and investments on various income groups to be made more transparent.

The revised [European Social Fund Plus \(ESF+\)](#), with a budget of EUR 88 billion from the [Multiannual Financial Framework 2021–2027](#), will help to reduce inequalities. The ESF+ will contribute to equal opportunities for children, a fair start for young people, more inclusive labour markets, and social integration for more disadvantaged people.

The Commission has committed to making progress towards a Union of Equality and

has adopted five equality strategies in 2020 and 2021. These include the [Gender Equality Strategy 2020–2025](#), the [LGBTIQ Equality Strategy 2020–2025](#), the [EU anti-racism action plan 2020–2025](#), the [EU Roma strategic framework for equality, inclusion and participation](#) and the [Strategy for the Rights of Persons with Disabilities 2021–2030](#).

Inequalities between countries

By reducing disparities in the levels of development of European regions, the [European Regional Development Fund](#) strengthens economic and social cohesion in the EU.

The [2021–2027 EU Cohesion Policy](#) focuses on five main objectives that drive investments to ensure all EU regions participate in the green and digital transitions in a fair and territorially balanced way.

Migration and social inclusion

The European Commission's [New Pact on Migration and Asylum](#) aims to create faster migration processes and stronger governance of migration and border policies.

The European Commission's [Action Plan on Integration and Inclusion](#) (2021–2027) sets out actions that support migrants' inclusion in education and employment, as well as access to health services and affordable housing.

The [EU Skills Profile Tool for Third Country Nationals](#) assists displaced persons, migrants and citizens of non-EU countries in profiling their skills and work qualifications to reception, employment and education services.

Reduced inequalities in the EU: overview and key trends

Inequalities within countries

High levels of inequality harm society in many ways. They can hamper social cohesion, result in lost opportunities for many, hinder economic activity, reduce social trust in institutions, lead to disproportionate exposure to adverse environmental impacts such as climate change and pollution, and undermine democratic participation ⁽¹⁾. Technological innovation and financial globalisation in particular have driven inequality within countries by favouring people with specific skills or accumulated wealth ⁽²⁾. Similarly, the transition to a climate-neutral society will have to be managed well to prevent rising inequality.

The income gap between the rich and the poor in the EU remains large

Analysing income distribution is one of the ways to measure inequality within EU countries. The [income quintile share ratio](#) compares the income received by the 20 % of the population who have the highest [equivalised disposable income](#) with the income of the 20 % with the lowest equivalised disposable income. The higher this ratio, the bigger the income inequality between the bottom and the top ends of the income distribution. In the EU, this ratio had been decreasing in recent years, falling from 5.22 in 2014 to 4.89 in 2020. However, in 2021, this trend reversed, with the ratio rising again to 4.97. This means that in 2021 the richest 20 % of the EU population earned almost five times as much as the poorest 20 % ⁽³⁾.

In 2021, the income of the richest 20 % of the population in the EU was 4.97 times higher than that of the poorest 20 %

Reflecting the trend in the income quintile share ratio, the income share of the bottom 40 % of the population in the total equivalised disposable income had been increasing between 2014 and 2019, followed by a stagnation in 2020 and a decline in 2021 to 21.3 %. The recent deterioration for both the income quintile share ratio and the income share of the bottom 40 % in 2021 might reflect the first impacts of the pandemic. However, it needs to be noted that recent trends might also be affected by a methodological change in the data collection in 2020 in a number of Member States, in particular in Germany and France ⁽⁴⁾. Moreover, as data collected in 2021 refer to people's income in 2020, the extent of the recovery after the pandemic remains to be seen.

21.3% was the share of total income earned by the bottom 40 % of the EU population in 2021

Economic inequality affects children's long-term opportunities

Inequality is also of particular concern regarding the long-term outcomes and opportunities for children. It puts those affected at a disadvantage from the start in areas with long-lasting consequences, such as physical and mental health and education, thus undermining their development and human potential. To evaluate these disadvantages, indicators on several dimensions of childhood inequality of opportunity, such as income ⁽⁵⁾ and education ⁽⁶⁾, have been developed. The COVID-19 pandemic has had negative effects on children's physical and mental health and exacerbated societal inequality ⁽⁷⁾. Moreover, there are wide variations between EU Member States regarding the childcare gap, which refers to a period in which

families with young children are unable to benefit from childcare leave or a guaranteed place in early childhood care. While some Member States experience no childcare gap (for example, Denmark and Slovenia), others offer a relatively short period of childcare leave and guarantee a place in early childhood care only relatively late in the child's life, at around 5 years of age (for example, the Netherlands and Ireland). Additionally, affordability of childcare remains an issue, especially for parents with multiple children and who are from low-income households ⁽⁸⁾.

The poverty gap and the at-risk-of-poverty-or-social-exclusion gap between urban and rural areas have narrowed in recent years

Inequality and poverty are closely interrelated. The poverty gap, defined as the distance between the median (equivalised disposable) income of people at risk of poverty and the [poverty threshold](#) (set at 60 % of the national [median](#) equivalised disposable income after [social transfers](#)), has decreased since 2016. In 2021, this gap amounted to 24.4 % in the EU, which means the median income of those below the poverty threshold was 24.4 % lower than the poverty threshold. This is a 1.0 percentage point narrowing of the gap since 2016, representing a moderate short-term improvement. However, relative to 2010, this gap has widened by 1.3 percentage points, indicating a longer-term deterioration in the 'depth' of monetary poverty in the EU.

Furthermore, the distribution of resources within a country has a direct impact on the extent and depth of poverty. In 2021, 21.7 % of the EU population were [at risk of poverty or social exclusion](#). However, this rate differs between cities and rural areas. In 2021, the urban–rural gap in the at-risk-of-poverty-or-social-exclusion rate amounted to 0.6 percentage points, with 21.9 % of people living in cities being in this situation,

compared with 22.5 % of people in rural areas. The lowest share of people at risk of poverty or social exclusion was observed in towns and suburbs, with 20.8 % of people at risk in 2021.

The gap in the risk of poverty or social exclusion rate between cities and rural areas at EU level has thus significantly narrowed compared with 2016, when it was 3.1 percentage points. This development is the result of a stronger improvement in rural areas, where the share of people at risk of poverty or social exclusion has fallen by 3.8 percentage points since 2016. In contrast, the rate in cities has decreased by only 1.3 percentage points over the same time span.

However, the overall EU figure masks the full scope of the broad variations in gaps among Member States. Rural poverty remains extremely high in some European countries, such as Bulgaria and Romania, where 42.5 % and 50.3 % of the rural population were at risk of poverty or social exclusion in 2021. This amounted to an urban–rural gap of 18.1 and 34.2 percentage points in these two countries, respectively. However, while rural areas generally tend to be at a higher risk of poverty due to out-migration and limited access to services, infrastructure, labour markets and educational opportunities ⁽⁹⁾, this does not account for all Member States.

Countries such as Austria, France and Belgium are reporting much higher poverty rates in cities than in rural areas.

Additionally, certain minorities such as Roma are at a much higher risk of monetary poverty. As of 2021, 80 % of Roma were at risk of monetary poverty, with their situation remaining unchanged since 2016. Moreover, 48 % of Roma were living in severe material deprivation in 2021, a reduction of 14 percentage points compared with 2016. Roma children under the age of 18 are particularly affected by poverty, with 83 % of those being at risk of poverty and 54 % living in households

with severe material deprivation in 2021. This further adds to the vulnerability of the Roma population ⁽¹⁰⁾.

The gap between the rich and the poor extends to their carbon footprint

In recent years, research has increasingly pointed to the greenhouse gas (GHG) emissions gap between the rich and the poor. This emissions gap highlights that the poorer sections of the society contribute less to the climate crisis. Research has shown that reaching the EU's 2030 target to reduce GHG emissions to at least 55 % below 1990 levels necessitates addressing carbon inequality within the EU ⁽¹¹⁾. Data from the World Inequality Database ⁽¹²⁾ show that in the EU, the carbon footprint, referring to per capita CO₂ emissions from consumption, of the richest 10 % of the population was 5.0 times higher than that of the poorest 50 % in 2020. The ratio has stagnated at this level since 2015. The Member States with the widest carbon footprint gap between the top 10 % and the bottom 50 % were Luxembourg, Romania and Austria, with ratios of 7.1, 6.5 and 6.3, respectively, in 2020. In comparison, the gap was the narrowest in Malta and the Netherlands, at 3.9 and 4.0, respectively. Overall, carbon footprint inequality in the EU is somewhat smaller than in other parts of the world. For example, the ratio amounted to 5.8 in Japan and 6.5 in the United States. A much higher carbon inequality was measured in India and China, with ratios of 10.2 and 12.6, respectively.

Inequalities between countries

We live in an interconnected world, where problems and challenges — such as poverty, climate change or migration — are rarely confined to one country or region. Therefore, combating inequalities between countries is important, not only from a social justice perspective, but also as a prerequisite for solving many interdependent problems. In particular, sharing prosperity and reducing trade barriers allow nations to cooperate on meeting global challenges, which by definition cannot be addressed by the EU alone (see chapter on SDG 17 'Partnerships for the goals' on

page 299). Cohesion between Member States is one of the EU's objectives, as mentioned in the [Treaty on European Union \(article 3.3\)](#).

North–south and west–east divides in economic disparities between EU countries remain

Not only have economic performance, incomes and living standards improved across the EU as a whole over time, they have also converged between countries. A way to measure such convergence is by looking at the coefficient of variation, expressed as the ratio of the standard deviation to the mean (in %). A lower coefficient of variation indicates less disparities between Member States. The two indicators used to measure this convergence show that inequalities between EU countries have decreased over the 15-year period assessed, even though the short-term trends are mixed.

The coefficient of variation in [gross domestic product \(GDP\)](#) per capita — expressed in [purchasing power standards \(PPS\)](#) — shows that economic disparities between Member States have narrowed since 2000, reaching 42.9 % in 2022. Most of this convergence took place in the period leading up to the 2008 economic crisis and between 2015 and 2019. However, during the COVID-19 crisis of 2020 and 2021, economic disparities between countries increased by 3.5 percentage points compared with the pre-pandemic levels of 2019. The coefficient of variation in GDP per capita returned to a downward trend in 2022, decreasing by 0.4 percentage points compared with 2021. At Member State level, purchasing power adjusted GDP per capita ranged from 59 % of the EU

average in Bulgaria to 261 % in Luxembourg in 2022.

While GDP per capita is used to measure a country's economic performance, adjusted gross **household disposable income** provides an indication of the average material well-being of people. Gross household disposable income reflects households' purchasing power and ability to invest in goods and services or save for the future, by taking into account taxes, social contributions and in-kind social benefits. The coefficient of variation in gross household disposable income between Member States has decreased over time, reaching 24.2 % in 2021. This figure is 3.2 percentage points less than in 2016 and a 9.8 percentage point improvement since 2006.

However, a clear north–south and west–east divide is evident when looking at the geographical distribution of GDP per capita and household income (from national accounts) in the EU in 2021. EU citizens living in northern and western European countries with above average GDP per capita levels had the highest gross disposable income per capita. At the other end of the scale were eastern and southern EU countries, which displayed gross household disposable incomes and GDP per capita levels below the EU average.

Migration and social inclusion

The Syrian conflict, unstable situations in Afghanistan and some African countries, crises in several Latin American countries such as Venezuela, Colombia, Honduras and Nicaragua, and the war in Iraq have contributed to an unprecedented surge of **migration** into the EU over the past few years. Russia's invasion of Ukraine has led to a mass influx of people fleeing the war to seek protection in the EU. The successful integration of migrants is decisive for the future well-being, prosperity and cohesion of European societies. To

ensure the social inclusion of immigrants and their children, it is essential to strengthen the conditions that will enable their participation in society, including their active participation in education and training and their integration into the labour market. Successful integration of migrants into the EU labour force has the potential to slow down the ongoing trend of population ageing and to address skills shortages.

The number of asylum applications in the EU has fallen considerably in recent years

The urge to seek international protection is one of the main reasons why people cross borders. In 2022, the EU received 881 220 first-time **asylum applications** ⁽¹³⁾, which is an almost 64 % increase since 2021. During 2022, slightly more than 310 000 people were granted protection status at the first instance in the EU ⁽¹⁴⁾. In relation to the EU population, these numbers equal 1 973 first-time asylum applications and 695 positive first-instance decisions per million EU inhabitants in 2022.

Following a considerable fall (by one-third) in the number of first-time asylum seekers applying for international protection between 2019 and 2020, owing to the COVID-19 pandemic and related emergency measures such as movement restrictions ⁽¹⁵⁾, the EU has since seen a consistent rise in asylum applications. The recent increase in first-time asylum applications and positive first instances can be attributed to the ongoing Russian invasion of Ukraine, which began in the first quarter of 2022. Following the displacement caused, the **Council Decision of March 2022** enabled non-EU citizens fleeing Ukraine to receive immediate and temporary protection. At the end of December 2022, close to 3.8 million displaced people were beneficiaries of this temporary protection in the EU ⁽¹⁶⁾. Poland and Germany, followed by Czechia, hosted the highest absolute number of

The monetary
poverty rate for
non-EU citizens
was
23.9
percentage
points higher
than for
home-country
nationals in the
EU in 2021

beneficiaries, providing temporary protection to around 61.8% of all beneficiaries in the EU.

Despite some improvements in recent years, the social inclusion of non-EU citizens remains a challenge

The social integration of migrants is monitored here by comparing the situation of non-EU citizens with citizens of EU Member States that reside in their home country —referred to as ‘home-country nationals’ in this publication — in the areas of poverty, education and the labour market. In all these areas, people from outside the EU fare less well than EU nationals. However, short-term trends have been mostly favourable, with the gap between home-country nationals and non-EU citizens closing or at least stagnating in almost all areas monitored here.

Trends in the citizenship gap for people at risk of [monetary poverty](#) after social transfers show that between 2016 and 2021, poverty rates remained quite stable for both non-EU citizens and EU home-country nationals. Still, the gap remains large, with 38.7% of non-EU citizens being at risk of monetary poverty (after social transfers) in 2021, compared with only 14.8% of home-country nationals.

Between 2017 and 2022, the employment rate for EU home-country nationals aged 20 to 64 increased by 3.4 percentage points, while the rate for non-EU citizens grew by 4.9 percentage points. As a result, the gap between the two groups has narrowed by 1.5 percentage points since

The
employment
rate for non-EU
citizens was
13.5
percentage

percentage
points higher
than for EU
home-country
nationals in
2022

2017. While 75.4% of EU home-country nationals were employed in 2022, the rate for non-EU citizens stood at 61.9%. Thus, despite the stronger improvement for non-EU citizens since 2017, the gap remains considerable, at 13.5 percentage points in 2022.

The gaps between home-country nationals and non-EU citizens in the area of education and training have evolved differently in recent years. The shares of young people not in employment nor in education and training (NEET) decreased for both groups between 2017 and 2022. The NEET rate for 15- to 29-year old non-EU citizens fell by 4.2 percentage points, reaching 22.3% in 2022. For home-country nationals of the same age, the NEET rate decreased by 1.9 percentage points in the same period, amounting to 10.9% in 2022. Thus, a narrowing of the gap by 2.3 percentage points has been visible since 2017. Despite these improvements, the citizenship gap between the two groups still amounted to 11.4 percentage points in 2022.

The share of
early school
leavers among
non-EU citizens
was
17.8
percentage
points higher
than for EU
home-country
nationals in
2022

The most striking difference between non-EU citizens and EU home-country nationals is visible for 18- to 24-year old early leavers from education and training. The early leaving rate of home-country nationals has fallen continuously since 2017, reaching 8.3% in 2022. In contrast, the early leaving rate for non-EU citizens increased by 0.8 percentage points over the same period, reaching 26.1% in 2022. As a result, the citizenship gap has widened by 1.9 percentage points since 2017, reaching 17.8 percentage points in 2022. Because early school leaving and unemployment both have an impact on people's future job opportunities and their lives in general, further efforts are needed to fully integrate young migrants into European societies.

11

Make cities and human settlements inclusive, safe, resilient and sustainable

SDG 11 aims to renew and plan cities and other human settlements in a way that offers opportunities for all, with access to basic services, energy, housing, transportation and green public spaces, while reducing resource use and environmental impacts.

Around 325 million people or almost three-quarters of the EU population live in urban areas — cities, towns and suburbs — with almost 40 % residing in cities alone ⁽¹⁾. With the share of Europe's urban population projected to rise to just over 80 % by 2050 ⁽²⁾, sustainable cities, towns and suburbs are therefore essential for citizens' well-being and quality of life. Monitoring SDG 11 in an EU context means looking at developments in the quality of life in cities and communities, sustainable mobility and adverse environmental impacts. Overall, the EU has made only modest progress towards SDG 11 over the past few years. While there has been strong progress in increasing the quality of life in cities and communities, trends in the area of sustainable mobility are less clear-cut and are moreover impacted by the COVID-19 pandemic. The picture is similarly diverse when it comes to adverse environmental impacts, with both sustainable and unsustainable trends visible.

Policy context

Quality of life in cities and communities and environmental impacts

Under the [EU Cohesion Policy](#), a minimum of 8% of the European Regional Development Fund of each national envelope is dedicated to supporting sustainable urban development. This is accompanied by the [European Urban Initiative](#) supporting innovation, capacity and knowledge-building in urban areas.

The [Environmental Noise Directive](#) is the main EU instrument for identifying and combatting noise pollution.

The EU addresses air pollution directly through specific legislation on air quality and emission sources, such as the [Clean Air Package](#), and indirectly by implementing certain climate policies to reduce pollution. The [EU emission standards for road vehicles](#) will further help improving air quality in cities.

The [affordable housing initiative](#) is part of the Commission's [renovation wave](#) strategy and ensures that social and affordable housing facilities also benefit from the wave.

The Action Plan 'Towards Zero Pollution for Air, Water and Soil' includes the target of reducing the health impacts due to air pollution by 55% by 2030, compared with 2005. The 2022 [Zero Pollution package](#) proposed stricter rules for cleaner air and water.

The [EU Soil Strategy for 2030](#) sets out a framework and concrete measures for protecting and restoring soils, and ensuring

they are used sustainably. The strategy contains a goal of no net land take by 2050.

The 2015 [Circular Economy Package](#) supports the transition to a stronger and more circular economy. In 2018, the legally binding [targets](#) for recycling and reuse of municipal waste [entered into force](#). EU countries will now be required to recycle at least 55% of their municipal waste by 2025, 60% by 2030 and 65% by 2035. The 2022 [Circular Economy package](#) aims to reduce packaging waste and increase recycling.

The [New European Bauhaus](#) initiative brings citizens, experts, businesses and institutions together to reimagine sustainable living in Europe and beyond, along the values of sustainability, aesthetics, and inclusion.

Sustainable mobility

The EU [guidelines for sustainable urban mobility](#) planning and funding for related projects, combined with the [Sustainable and Smart Mobility Strategy](#) adopted in 2020, support the green and digital transformation of the EU transport system.

The [Communication on the Urban Mobility Framework](#) (2021) reinforces the EU framework for Member States, enabling regions and cities to develop safe, accessible, inclusive, smart, resilient and zero-emission urban mobility.

The [Strategic Action Plan on Road Safety](#) and the [EU road safety policy framework 2021–2030](#) set a 50% reduction target for deaths and for serious injuries by 2030 compared with 2019 and ambitious road safety plans to move close to zero road deaths by 2050 ('Vision Zero').

Sustainable cities and communities in the EU: overview and key trends

Quality of life in cities and communities

While European cities and communities provide opportunities for employment, as well as economic and cultural activity, many inhabitants still face considerable social challenges and inequalities. Problems affecting the quality of housing and the wider residential area, such as noise disturbance, crime and vandalism, are some of the most visible challenges that cities and communities can face and which impact quality of life.

Quality of housing in the EU has improved since 2010

Safe and adequate homes are a foundation for living an independent, healthy and fulfilling life. Poor housing conditions, on the other hand, are associated with lower life chances, health inequalities, increased risks of poverty and exposure to environmental hazards.

The severe housing deprivation rate refers to the share of the population living in an **overcrowded** household while also experiencing types of housing deprivation such as a leaking roof, damp walls, floors or foundations; rot in window frames or floors; lacking sanitary facilities; or a **dwelling** that is considered too dark. Between 2010 and 2020, the share of EU residents who lived in such conditions fell by 1.8 percentage points, which indicates an improvement in the perceived quality of the EU's housing stock.

Europeans perceive their residential areas as quieter and safer

Noise disturbance can cause annoyance, stress, sleep deprivation, poor mental health and well-being, as well as harm to the cardiovascular and metabolic system ⁽³⁾. Likewise, crime and vandalism can also reduce quality of life and housing satisfaction in a residential area. In 2020, 17.6% of the EU population (about 78 million people) said their household suffered from noise disturbance, compared with 20.6% in 2010 ⁽⁴⁾. Crime, violence and vandalism in the neighbourhood were perceived by 10.7% of the EU population in 2020, compared with 13.1% in 2010.

17.6 %
of the EU
population
experienced
noise
disturbance in
2020

The EU's zero pollution action plan aims to reduce the share of people chronically disturbed by transport noise by 30% by 2030 compared with 2017. At 55 decibels (dB) noise levels can start to have critical effects, ranging from severe annoyance and sleep disturbance to hearing impairment ⁽⁵⁾. The more recent [WHO guidelines for Europe](#) are even more stringent, recommending that the noise level from road traffic should be below 53 dB during the day and below 45 dB at night. Despite improvements in perceived exposure to noise, 95 million people in the EU were estimated to be exposed to road traffic noise at levels of 55 dB or higher on an annual average for day, evening and night in 2017. While railways and airports represent further significant sources of local noise pollution, their impact on the overall population is much lower. The number of people exposed to harmful noise levels has not decreased significantly since 2012 ⁽⁶⁾. A recent [outlook from the European Environment](#)

Agency (EEA) suggests that meeting the 30 % reduction target of the zero pollution action plan will be challenging, with the most optimistic scenario only estimating a 19 % reduction by 2030.

Exposure to fine particulate matter in the EU leads to premature deaths

Pollutants such as fine [particulate matter](#) (PM_{2.5}) suspended in the air reduce people's life expectancy, and can lead to or aggravate many chronic and acute respiratory and cardiovascular diseases ⁽⁷⁾. Exposure to air pollution is of particular concern in cities, as they contain both a large number of potential emission sources (due to the concentration of economic activities) and large number of people being affected by air pollutants (due to the high population density).

According to [data from the EEA](#), in 2020 almost all EU Member States registered annual mean PM_{2.5} concentrations below the EU limit value of 25 µg/m³ ⁽⁸⁾. This effect is partly due to lockdown measures introduced by most governments during the COVID-19 pandemic.

However, when considering the more stringent 2021 WHO air quality guideline of 5 µg/m³, almost all EU city dwellers (96 %) were estimated to be exposed to PM_{2.5} concentration levels deemed harmful to human health. The European Commission has [proposed aligning EU ambient air quality standards](#) more closely with WHO recommendations, and improving air quality monitoring, modelling and plans.

In the EU, long-term exposure to fine particulate matter was responsible for around 238 000 premature deaths in 2020. Since 2005, the number of premature deaths has already fallen by around 45 %, and the EU thus appears on track to meeting the zero pollution action plan target for 2030, which aims to reduce the number of premature deaths due to fine particulate matter exposure by more than 55 % compared with 2005 ⁽⁹⁾. However,

achieving the zero pollution target would require Member States to successfully implement current and planned policies, including the climate and energy targets put in place by the EU for 2030 ⁽¹⁰⁾.

City dwellers experience more noise pollution and crime

Statistics on the [degree of urbanisation](#) provide an analytical and descriptive lens through which to view urban and rural communities. Based on the share of the local population living in urban clusters and urban centres, Eurostat differentiates between three types of area: 'cities', 'towns and suburbs' and 'rural areas' ⁽¹¹⁾.

The severe housing deprivation rate in the EU in 2020 was higher in rural areas (4.9 %) than in cities (4.8 %) and in towns and suburbs (3.4 %) ⁽¹²⁾.

The perceived level of noise pollution varied greatly depending on the degree of urbanisation. In 2020, people living in EU cities were more likely to report noise from neighbours or from the street (23.9 %) compared with those living in towns and suburbs (16.3 %) or in rural areas (10.5 %) ⁽¹³⁾. Similarly, the perceived occurrence of crime and vandalism in cities (16.3 %) was almost three times higher than in rural areas (5.8 %) and above the level observed in towns and suburbs (8.4 %) in 2020 ⁽¹⁴⁾.

cities reported
occurrence
of crime and
vandalism in
their area in
2020

Only two-thirds of the EU's urban population can enjoy green urban spaces within walking distance

Green spaces in cities have a great potential to boost human health and well-being, and play a crucial role for children, the elderly and those with lower incomes, who may otherwise have limited access to nature. Universal accessibility to green spaces that are safe, inclusive and open is thus essential. In the EU, 66.7 % of the urban centre population had access to green urban areas within a 400-metre walk in 2018. This share has remained

stable since 2012. When considering green urban areas that are at least one hectare large, only 56.3 % of the urban centre population had access within a 400-metre walk in 2018. Among the EU Member States, Finland held the largest share of urban population with access to a green space within walking distance (93.9 %) in 2018, while Cyprus had the lowest (26.1 %) ⁽¹⁵⁾.

Sustainable mobility

A functioning transport system is necessary for people to reach their places of work, education, services and social activities, all of which affect quality of life and equal opportunities for everyone. In addition to availability, the type, quality and safety of transport systems are also crucial when designing sustainable and inclusive cities and communities.

Use of public transport modes dropped considerably during the pandemic

The EU aims to improve citizens' quality of life and to strengthen the economy by promoting sustainable urban mobility and greater use of clean and energy-efficient vehicles, together with reducing the demand for individual car transport. Public transport networks help to relieve traffic jams, reduce harmful pollution and offer more affordable and sustainable ways to commute to work, access services and travel for leisure.

Since 2000, the share of buses and trains in inland passenger transport has stagnated well below 20 %, accounting for only 17.5 % in 2019. With the onset of the pandemic in 2020, this share fell drastically by 4.7 percentage points compared with 2019, to 12.8 %. The precautionary measures put in place, including domestic and international travel restrictions, quarantine restrictions, introduction of remote-working policies and changing mobility habits led to a reduction in the use of public transport ⁽¹⁶⁾ and passengers' perceptions about

safety and comfort. Consequently, the share of private mobility, including cycling, walking and private cars has increased. This decline in the shares of public modes of mobility is also reflected in the long- and short-term trends, showing a reduction by 4.6 percentage points since 2005 and by 4.8 percentage points since 2015.

Cars continue to remain the dominant form of passenger mobility in the EU. The decline in the use of public transport in 2020 coincides with an increase in the share of passenger kilometres travelled by car, which rose from 82.5 % in 2019 to 87.2 % ⁽¹⁷⁾. According to an [EU-wide survey on passenger mobility](#) carried out in 2021, 64 % of the respondents reported that their travel behaviour was impacted by the COVID-19 pandemic. The extent of the recovery of public transport modes relative to private ones — especially cars — thus remains to be seen for 2022 and beyond.

Deaths from road crashes have fallen, but greater progress will be necessary to meet the 2030 target

Road traffic injuries are a public health issue and have a huge economic cost. About 120 000 people are estimated to be seriously injured in road accidents in the EU each year ⁽¹⁸⁾. In 2021, about 55 people a day lost their lives on EU roads. This corresponds to slightly more than 19 900 people for the entire year — a loss equivalent to the size of a medium town.

Nevertheless, the EU has made considerable progress in this respect compared with 2002 and 2010, when road deaths amounted to about 50 000 and 30 000, respectively.

In recent years, the figures have experienced some fluctuations, in part explained by significant changes in traffic volumes as a result of the COVID-19 pandemic. Between 2020 and 2021, road traffic deaths increased by 6 % following an unprecedented fall of 18 % between 2019 and 2020. The most recent figures, based on [preliminary data for 2022](#), show the number of road deaths were 10 % lower than in relation

to 2019. However, while the underlying trend in relation to the pre-pandemic level continues to be downward, the EU as a whole is not on track to meet its **2030 target of halving the total death toll on EU roads** compared with 2019.

The highest share of road-traffic fatalities in 2021 was recorded on non-motorway roads outside urban areas (52 %), followed by roads inside urban areas (39 %) and motorways (9 %) ⁽¹⁹⁾. While the overall number of fatalities fell by 23.1 % between 2010 and 2019, the number of cyclists killed in urban areas actually increased by 3.1 % ⁽²⁰⁾. Indeed, EU-wide, almost 70 % of fatalities in urban areas involve vulnerable road users such as pedestrians, motorcyclists and cyclists. This is therefore a key area when it comes to introducing new policy measures to tackle road safety.

Environmental impacts

While cities, towns and suburbs are a focal point for social and economic activity, if not managed sustainably, they risk causing considerable environmental damage. At the same time, large and densely populated cities provide opportunities for effective environmental action, indicating that urbanisation is not necessarily a threat but can act as a transformative force for more sustainable societies ⁽²¹⁾. EU progress in reducing the environmental impacts of cities and communities is monitored by three indicators on the management of municipal waste, waste water treatment and artificial land cover.

The settlement area per capita has increased

Offering numerous cultural, educational and job opportunities, an urban lifestyle is attractive to many people. However, growth in the urban population has also come with increased land take. Land take is described as the process of transforming agricultural, forest and other semi-

natural and natural areas into artificial areas. It often means growth in the settlement area over time, usually at the expense of rural areas. As a result of land take, urban areas may severely hamper the functioning of ecosystems and the related delivery of ecosystem services ⁽²²⁾.

The settlement area indicator captures the amount of settlement area due to land take. In the EU, settlement area per capita has increased over the past few years. In 2018, for each EU inhabitant, 703.4 square metres (m²) of land was covered by settlement area (comprising both sealed and non-sealed surfaces — for example, buildings, industrial and commercial area, infrastructure as well as parks and sportsgrounds), which is 3.3 % more than in 2015.

Despite continuous improvements in municipal waste recycling, the EU might miss its targets

The 'waste hierarchy' is the overarching logic that guides EU waste policy. It prioritises waste prevention, followed by [preparing for reuse](#), [recycling](#), other [recovery](#), and finally disposal, including [landfilling](#), as the last resort. Waste management activities promote recycling, which reduces the amount of waste going to landfills and leads to higher resource efficiency. Although [municipal waste](#) accounts for less than 10 % of the weight of total waste generated in the EU ⁽²³⁾, it is highly visible and closely linked to consumption patterns. Sustainable management of this waste stream reduces the adverse environmental impact of cities and communities, which is why the EU has set a target to recycle or prepare for reuse at least 60 % of its municipal waste by 2030 ⁽²⁴⁾.

In 2021, the EU residents generated 236.8 million tonnes of municipal waste, corresponding to 530 kilograms (kg) of waste per capita per year ⁽²⁵⁾. Since 2016, the annual amount of waste

generated per capita increased by 37 kg, which represents an increase of 7.5 % between 2016 and 2021. Although the EU has not reduced its municipal waste generation, it has clearly shifted to more recycling. Since 2000, the recycling rate of municipal waste — covering both recycling and preparing for re-use — has increased continuously from 27.3 % to 49.6 % in 2021. However, the trend has slowed since 2016, with the share of recycled municipal waste increasing by only 3.7 percentage points between 2016 and 2021. Further efforts are therefore needed to put the EU back on track towards meeting its recycling targets by 2030.

Connection rates to waste water treatment have been increasing

Urban areas also place significant pressure on the water environment through waste water from households and industry that contains organic matter, nutrients and hazardous substances. The share of the EU population [connected to at](#)

[least secondary waste water treatment plants](#), which decompose most of the organic material and retain some of the nutrients, has been steadily growing since 2000 and reached 81.1 % in 2020. In seven Member States, more than 90 % of the population were connected to such services according to most recent data (which refer to 2015, 2019 or 2020, depending on the country). However, it may not be suitable to connect 100 % of the population to a sewerage collection system, either because it would produce no environmental benefit or would be too costly (see chapter on SDG 6 'Clean water and sanitation' on page 119).

81.1 %
of the EU
population were
connected to at
least secondary
waste water
treatment in
2020

12

Ensure sustainable consumption and production patterns

SDG 12 calls for a comprehensive set of actions from businesses, policy-makers and consumers to adapt to sustainable practices. It envisions sustainable production and consumption based on advanced technological capacity, resource efficiency and reduced global waste.

Consumption and production patterns have wide environmental and social impacts. Monitoring SDG 12 in an EU context focuses on developments in the areas of decoupling environmental pressures from economic growth, the green economy, and waste generation and management. Overall, the EU's progress towards this goal over the five-year period assessed has been mixed. While consumption of raw materials and energy productivity have shown positive developments, consumption of hazardous chemicals has increased. The picture is also mixed in the area of waste generation, where circular use of materials is not growing fast enough to meet the target, despite reduced waste generation. On a positive note, the value added from the environmental goods and services sector has been growing.

Policy context

The [8th Environment Action Programme \(EAP\)](#) aims to accelerate the transition to a climate-neutral, resource-efficient and regenerative economy, recognising that human well-being depends on healthy ecosystems.

The [Circular Economy Action Plan](#) from 2020 aims to double the EU's circular material use rate in the coming decade to support the achievement of climate neutrality by 2050, to decouple economic growth from resource use and waste generation and to keep resource consumption within ecological boundaries. In 2022, the European Commission proposed a [package on Circular Economy measures](#) to make sustainable products the norm in the EU and boost circular business models. The [Council Recommendation on ensuring a fair transition towards climate neutrality](#) calls for facilitating access to sustainable consumption, such as affordable reuse, repair, recycle and sharing schemes, especially for people and households in vulnerable situations.

The [Recovery and Resilience Facility](#) supports reforms and investments to boost sustainable consumption and production patterns, for example in the areas of sustainable mobility and circular economy.

The [Global Alliance on Circular Economy and Resource Efficiency](#) brings together governments and relevant organisations to advance the circular economy transition.

The [New Consumer Agenda](#) aims to empower consumers to engage with the green and digital transitions while enforcing consumer rights and protection.

The revised [Waste Framework Directive](#) sets a goal to reduce food waste by 30 % by 2025 and 50 % by 2030. It also establishes a 55 %

recycling rate target for municipal waste that will be increased to 65 % by 2035 and emphasises waste prevention.

The 2020 [EU industrial strategy](#) and its 2021 update aim to help Europe's industry lead the twin transitions towards climate neutrality and digital leadership. The [Green Deal Industrial Plan](#) aims to enhance the competitiveness of Europe's net-zero industry and support the fast transition to climate neutrality.

The [REACH](#) framework aims to protect human health and the environment through better identification and management of hazardous chemicals. The framework will be updated in 2023, supported by the [Chemicals Strategy for Sustainability](#), which aims to reduce the harm to humans and the environment from exposure to chemicals.

The 2021 [Zero Pollution Action Plan](#) calls for air, water and soil pollution to be reduced to levels no longer considered harmful to health and ecosystems, respecting planetary boundaries and creating a toxic-free environment. In 2022 the Commission adopted a [Zero Pollution package](#) proposing stricter rules for cleaner air and water.

EU legislation sets mandatory [CO₂ emission targets for cars and vans](#) and [CO₂ emission standards for heavy-duty vehicles](#) applying from 2025. A recently adopted [Regulation strengthens the CO₂ emission performance standards for new passenger cars and new light commercial vehicles](#). The revised [Clean Vehicles Directive](#) promotes clean mobility solutions in public procurement. In addition, the [Smart and Sustainable Mobility Strategy](#) from 2020 aims to contribute to the [2030 and 2050 climate targets](#) and the [zero pollution ambition](#) by making at least 30 million zero-emission cars operational in Europe by 2030.

Responsible consumption and production in the EU: overview and key trends

Decoupling environmental pressures from economic growth

Economic growth improves people's well-being but has long been associated with growing resource and energy consumption. Continuous growth in the consumption of finite resources both harms the environment and significantly contributes to climate change. To tackle this challenge, the EU has launched a new growth strategy — the [European Green Deal](#) — which aims to transform the EU into a fair and prosperous climate-neutral society, with a modern, resource-efficient and competitive economy where economic growth is decoupled from resource use. It focuses on improving resource- and energy-use efficiency by restructuring economies so they produce more from the same resource and energy inputs.

The EU's material footprint reached a new low in 2020 due to a 5.6 % decrease in the pandemic year

The material footprint, also referred to as raw material consumption (RMC), shows the amount of materials used along the supply chains of goods and services that are finally consumed in a country. The indicator thus measures the extracted materials (both domestic and abroad) needed to produce goods and services consumed by final users inside EU borders and estimates the volume of traded products — imports and exports — in raw material equivalents.

The EU's material footprint had been growing between 2013 and 2019, before falling by 5.6 % in 2020 compared with the previous year. In absolute terms, final users in the EU consumed 6.11 billion tonnes of raw material (in raw material equivalents) in 2020, which translates into a per-capita material footprint of 13.7 tonnes. The most recent drop in the material footprint is likely to be the result of reduced economic activity during the pandemic

and has led to the lowest RMC value recorded for past two decades. Nevertheless, the significant increase in the EU's material consumption up to 2019 suggests further efforts might be required to meet the objectives of the European Green Deal, which calls for a reduction in environmental pressures alongside economic growth (also see the section on spillover effects on page 335).

The [Consumption Footprint](#) — a set of 16 indicators developed by the European Commission's Joint Research Centre (JRC) to quantify the environmental impacts of the EU's consumption — also reveals the need for further efforts to reduce consumption and achieve the EU's policy goals. The results show the EU is responsible for a significant amount of environmental impacts outside its borders. The environmental impact of the EU's consumption within the EU and abroad also increased by around 4 % between 2010 and 2021, due to growth in the amount of consumed goods. The largest increases occurred in the consumption of food (18 %), appliances (5 %) and household goods (5 %) (1).

6.11 billion tonnes of globally extracted raw material were consumed in the EU in 2020

More than half of fossil energy carriers and metal ores used in the EU are imported

Data on material import dependency reveal the extent to which an economy relies on imports to meet its material needs. Material import dependency is calculated as the ratio of imports to [direct material input](#) (DMI), which is the sum of imports and domestic extraction. In 2021, imports accounted for 22.9 % of the EU's DMI. Import dependency was highest for fossil energy carriers, at 70.7 % in 2021, followed by metal ores at 51.7 %. The EU's import dependency on fossil energy

carriers has increased by about 10 percentage points over the past decade (up from around 60 %), while dependency on metal ore imports has remained stable. In contrast, the EU is almost completely self-sufficient for non-metallic minerals, with an import dependency of only 3.3 % in 2021 ^(?).

The EU's self-sufficiency is especially relevant for **critical raw materials (CRMs)**, which refer to raw materials that are of high importance to the EU economy combined with a high risk associated with their supply. To address the challenge of ensuring reliable and unhindered access to certain raw materials, the European Commission presents a list of critical raw materials that is reviewed every three years. The **CRM list from 2023** contains 34 materials; data on the EU's self-sufficiency are available for eight of them. They show that the EU's self-sufficiency was highest for copper (62.3 % in 2018), lithium (30.1 %), fluor spar (29.0 %) and aluminium (9.8 %). However, the EU economy was (almost) completely dependent on imports for borate (0.0 % self-sufficiency), cobalt (2.6 %), natural graphite (0.3 %) and tantalum (0.0 %) ^(?). To ensure access to a secure and sustainable supply of the critical raw materials needed for the EU to meet its 2030 climate and digital objectives, the Commission has proposed a **Critical Raw Materials (CRM) Act**. This would set benchmarks for domestic capacities, such as for extraction or recycling, to be met by 2030.

Resource and energy productivity have increased in the EU over the five-year period assessed

Resource productivity ⁽⁴⁾ monitors how much output an economy produces per unit of used materials and can provide insights into whether decoupling between the use of natural resources and economic growth is taking place. It is measured as the ratio of **gross domestic product (GDP)** to **domestic material consumption (DMC)**. Between 2016 and 2021, the EU economy (in terms of GDP) grew by 6.3 %, while DMC grew at a slower pace, by 4.5 % over the same period. This resulted in a 1.4 % increase in the EU's resource productivity, from EUR 2.06 per kilogram (kg) of DMC in 2016 to EUR 2.09 per kg in 2021 ⁽⁵⁾.

Similar to resource productivity, **energy productivity** ⁽⁶⁾ measures economic output (in terms of GDP) per unit of energy used. Observed trends for energy productivity are stronger than for resource productivity, due to larger decreases in energy consumption than in material use. Between 2016 and 2021, the EU increased its energy productivity by 9.1 %, from EUR 7.8 per kg of oil equivalent (kgoe) to 8.5 EUR per kgoe. Over the same period, economic growth of 6.3 % in the EU was accompanied by a reduction in gross available energy (GAE) of 2.6 % ^(?). However, energy productivity decreased by 0.7 % in 2021 compared with the previous year, due to an increase in GAE.

In 2021, the EU's energy productivity amounted to

8.5
EUR per kgoe

Consumption of hazardous chemicals has been increasing

Most everyday products used by businesses and consumers are produced with the help of chemicals. This makes them a significant contributor to the EU economy, with chemical sales worth EUR 594 billion in 2021 ⁽⁸⁾. The consumption of chemicals provides benefits to society but can also entail environmental and health risks. The level of risk depends on both the hazard presented by the chemicals and exposure to them. Tracking the consumption volumes of industrial (manufactured) chemicals that are hazardous to human and environmental health is, therefore, used as a proxy for human exposure ⁽⁹⁾.

226.0
million tonnes
of toxic
chemicals were
consumed in
the EU in 2021

In 2021, 226.0 million tonnes of hazardous chemicals were consumed in the EU. This is 8.3 % less than the amount consumed in 2006. However, the short-term trend appears more negative, with consumption increasing by 5.0 % between 2016 and 2021.

Average CO₂ emissions from new car fleets have fallen over the past decade

Passenger cars are responsible for a considerable share of the EU's total greenhouse gas (GHG) emissions. To reduce those emissions, the EU has set targets for the fleet-wide average emissions of new passenger cars. For each manufacturer's new car fleet, a binding specific emission target is set according to the average mass of its new vehicles, in such a way that the overall target for the EU's average fleet emissions will be met.

Between 2007 and 2020, data on the average CO₂ emissions per km from new passenger cars were collected based on the New European Driving Cycle (NEDC) procedure. In 2021, data collection for the first time was based on the World Harmonised Light-vehicle Test Procedure (WLTP) procedure. Compared to the former NEDC procedure, this leads to higher emission values that are more representative of vehicles' emissions when they are used on the road. To ensure manufacturers' targets are equally stringent, these have been converted to represent WLTP rather than NEDC conditions.

Data collected according to NEDC show that average CO₂ emissions per km from new passenger cars registered in the EU fell almost continuously between 2007 and 2020, reaching 107.9 grams per kilometre (g/km). This is a 9.4 % reduction over the five-year period since 2015. The most recent data collected according to WLTP show average CO₂ emissions per km from new passenger cars were 116.3 g/km in 2021.

Replacing conventional cars with zero emission vehicles will be a crucial step towards achieving the EU's greenhouse gas emission reduction targets, as set out in the [European Climate Law](#) and the EU's [2030 Climate Target Plan](#), and towards climate neutrality by 2050. According to data from the [European Alternative Fuels Observatory](#) and statistics from Member States, the share of zero-emission vehicles (including both battery

116.3
grams of CO₂
per km
were emitted on
average by new
passenger cars
in the EU in 2021

electric vehicles and hydrogen vehicles) in newly registered passenger cars in the EU rose from 0.5 % in 2016 to 9.4 % in 2021. Preliminary data for 2022 show further growth to about 12 %. However, the share differs considerably between European countries. Within the EU, the Netherlands reported the highest share with 19.8 % in 2021, followed by Sweden with 19.0 % and Austria with 13.9 %. In contrast, zero-emission vehicles accounted for less than 1 % of newly registered passenger cars in Bulgaria and Cyprus ⁽¹⁰⁾.

Green economy

Another way to help decouple environmental impacts from economic growth is to increase the share of the green economy. The environmental goods and services sector (EGSS) is the part of the economy that produces the goods and services used in environmental protection and resource management activities. Such goods and services can include, for example, products to prevent, measure, control, limit, minimise or correct environmental damage and resource depletion. Increasing the market share of green technologies in the EU can also have important socio-economic benefits in terms of value added and employment ⁽¹¹⁾.

300.1
billion EUR
of gross value
added were
generated
by the EU's
environmental
goods and
services sector
in 2020

The increase in the value added of the environmental goods and services sector has outpaced overall economic growth

The gross value added in the EGSS in the EU has grown by 68.6 % over the 15-year period assessed, from EUR 178.0 billion in 2005 to EUR 300.1 billion in 2020. Growth in the renewable energy and energy efficiency sectors, along with increased spending on green infrastructure, are among the main drivers of this development ⁽¹²⁾. In relation to the whole economy, the EGSS grew — in gross value added terms — from 1.7 % of GDP in 2005 to 2.5 % in 2020. This indicates the sector grew

disproportionally faster than other economic sectors. Notably, the sector's gross value added continued to grow in 2020, by 1.9%, when the EU's GDP fell by 5.6% as a result of the COVID-19 pandemic. Employment (in [full-time equivalent](#)) in the sector has also increased, by 47.5%, since 2005. In 2020, the sector provided around 5 million full-time equivalent jobs throughout the EU ⁽¹³⁾.

Waste generation and management

Production and consumption patterns characterised by products being made, used and disposed of at an ever-faster rate are not sustainable. Therefore, the EU aims to move towards a circular economy where materials and resources are kept in the economy for as long as possible (through repair, recycling and reuse) and [waste](#) is minimised or even prevented. Because waste contains resources, [recycling](#) can put these materials back into the economy and ensure they are used again to preserve the value embedded within them.

Waste generation has fallen, but the EU is not on-track to meet its circular material use goal

In 2020, 2.2 billion tonnes of waste were generated in the EU by all economic activities and households, corresponding to 4 813 kg of waste per inhabitant. Almost two-thirds (64.0% or 3.1 tonnes per inhabitant) of this waste was major mineral waste, including dredging spoils and contaminated soils that are mainly created in the mining and construction sectors. Of the total waste, 4.4% was hazardous to health or the environment, corresponding to 214 kg per resident in 2020. Overall, the amount of waste generated in the EU fell by 4.7% between 2016 and 2020, likely as a result of the pandemic-related economic slowdown in 2020.

Total waste excluding major mineral waste constituted one-third (36%) or 775 million tonnes

4 813 kg
of waste were
generated
in the EU per
inhabitant in
2020

of total waste generated in the EU in 2020. From this amount, 212 million tonnes were recorded for waste and water services, followed by households (196 million tonnes) and manufacturing activities (167 million tonnes). In 2020, food waste accounted for 59 million tonnes in the EU. More than half (53.5%) of food waste was generated by household activities, followed by manufacture of food products and beverages (20.2%) and primary production of food (10.4%) ⁽¹⁴⁾.

When not managed sustainably, all of this waste has a huge impact on the environment, causing pollution and greenhouse gas emissions, and significant losses of materials ⁽¹⁵⁾. Recycling waste and feeding it back into the economy as secondary raw materials is crucial for reducing the EU's demand for primary raw materials and relies heavily on improved waste management systems ⁽¹⁶⁾.

Between 2006 and 2021, the EU circular material use (CMU) rate — the share of used materials derived from collected waste — increased from 9.1% to 11.7%. Since 2019, however, the CMU rate has fallen by 0.3 percentage points, meaning the EU will need to make stronger progress in the next few years to meet its goal of 23.4% of the materials it uses coming from collected waste by 2030.

Data for the recycling of waste excluding major mineral wastes show that 58% of EU waste was recycled in 2020 ⁽¹⁷⁾. The difference between this relatively high end-of-life recycling rate and the CMU rate (11.7% in 2021) may seem surprising. However, the comparatively low degree of circularity in the EU can be attributed to two structural barriers. First, a large fraction of the materials extracted, in particular minerals, is used to build and maintain buildings, infrastructure and other long-life goods and is not readily available for recycling. The second barrier is the large amount of materials used to generate energy. For these materials, in particular for fossil fuels, closing the loop is hardly possible and the high share of these materials keeps the degree of circularity low ⁽¹⁸⁾.

11.7%
of the materials
used in the
EU came from
collected waste

Take urgent action to combat climate change and its impact

SDG 13 seeks to achieve a climate-neutral world by mid-century and to limit global warming to well below 2°C — with an aim of 1.5°C — compared with pre-industrial times. It aims to strengthen countries' climate resilience and adaptive capacity, with a special focus on supporting least-developed countries.

Climate change increases global air and ocean temperatures, changes precipitation patterns, raises the global average sea level, provokes extreme weather events, harms biodiversity and increases ocean acidity. Its impacts threaten the viability of social, environmental and economic systems and may make some regions less habitable due to food and water scarcity. Monitoring SDG 13 in an EU context focuses on climate mitigation, climate impacts and initiatives to support climate action. As surface temperatures rise, the EU faces intensifying climate impacts and economic losses from climate-related events which have increased in recent years. Though net greenhouse gas (GHG) emissions partly bounced back in 2021 after falling during the peak of the COVID-19 pandemic in 2020, they remained below their 2019 levels. However, more effort will still be needed to reach the ambitious target of reducing net GHG emissions by 55 % by 2030. These additional efforts are already foreseen in the Fit for 55 package with a revision of the EU emissions trading system (ETS) and the effort-sharing regulation that sets binding annual GHG emissions targets for Member States. The 2030 target includes net GHG removals from land use, land use change and forestry, which have continued to decline and thus have contributed less to progress

towards the net GHG target. The share of renewables has kept rising in the EU, but stronger progress will be needed to meet the new, more ambitious 2030 target. More local and regional governments have joined the Covenant of Mayors for Climate and Energy initiative for implementing mitigation and adaptation actions. Significant progress has also been made on financial support, with climate-related expenditure for developing countries being topped up.

Table 13.1: Indicators measuring progress towards SDG 13, EU

Note: See Annex I for a description of the methodology used for the growth rate calculation and the trend assessment. For indicators without a target, the growth rates observed over the specified periods are given. For indicators with a quantified EU target, both the observed growth rates and the growth rates that would have been required in the specified periods for meeting the target are given.

(*) Multi-purpose indicator.

⁽¹⁾ Assessed against the 55 % net emission reduction target for 2030. Note that this assessment is based on past progress and not on projections of future emissions based on planned legislation and policy measures.

⁽²⁾ Assessed against the 310 Mt CO₂-equivalent target for 2030. Note that carbon removals in 2006 were already above the target value but have decreased at a higher rate than what would have been allowed to remain on top of this level.

⁽³⁾ Assessment against the new target of increasing the share of renewables to 42.5 % by 2030, agreed in March 2023.

Policy context

Climate mitigation

The EU signed the [Paris Agreement](#) in 2015. The European [Climate Law](#) establishes the goal to reduce net GHG emissions by at least 55 % between 1990 and 2030 and to achieve climate-neutrality by 2050, the key objective of the [European Green Deal](#).

In 2021, the European Commission proposed a package of new and revised EU climate and energy legislation — the so-called [Fit for 55](#) package. The package comprises an interconnected set of measures and includes strengthened and expanded carbon pricing, targets, standards and support measures. It also sets a target for natural carbon sinks of 310 million tonnes of CO₂ equivalents. Some of these measures have been adopted already, while for others there are provisional agreements in place or the discussions are still ongoing.

The [Just Transition Mechanism](#) supports regions that are the most carbon-intensive or with the most people working in fossil fuels. The [Social Climate Fund](#) will support vulnerable households, micro-enterprises and transport users to cope with price impacts of emissions trading in road transport and buildings.

Climate impacts and adaptation

The EU [Adaptation Strategy](#) urges smarter, faster and more systematic adaptation so that by 2050 the EU will have become a climate-resilient society, fully adapted to the unavoidable impacts of climate change. The [Climate Law](#) mandates continuous progress in enhancing adaptive capacity, strengthening resilience and reducing vulnerability.

The EU [Action Plan for the Sendai Framework for Disaster Risk Reduction](#) includes climate change adaptation actions carried out at both the EU and international level, linking these to disaster risk-reduction strategies and their coherent implementation. In addition, the [EU Civil Protection Mechanism](#) steps in to aid Member States that are in a state of emergency due to disaster, if their national capacities are lacking.

Financing climate action

Support to climate action in the EU comes from the [EU budget](#), the [Recovery and Resilience Facility](#) and climate-related funds including the [Innovation and the Modernisation Funds](#). To shift private and public investments towards sustainable activities, the EU introduced a [taxonomy for sustainable economic activities](#), requesting [sustainability-related disclosures](#) to investors for financial products and establishing two new climate-friendly [benchmarks for investment portfolios](#). Further work is summarised in the Commission's [strategy for financing the transition](#).

The [REPowerEU Plan](#) will bring EUR 210 billion additional investment in energy efficiency, energy infrastructure and renewable energy. The new [Green Deal Industrial Plan](#) includes major support to solar panels, wind turbines, heat pumps, hydrogen, energy storage, electric vehicles and critical raw materials extraction, processing and recycling.

To support developing countries, the EU and its Member States contribute to the joint goal of developed countries under the Paris Agreement to [provide USD 100 billion per year](#) in climate finance through to 2025.

Climate action in the EU: overview and key trends

Climate mitigation

Climate mitigation aims to reduce emissions of climate-harming **greenhouse gases** (GHG) that originate from human activity through measures such as promoting low-carbon technologies and practices or encouraging sustainable forest management and land use that enhance carbon removals. The EU has set into **law** a target to reach climate neutrality with no net GHG emissions by 2050. This means reducing GHG emissions as much as possible while offsetting the residual emissions by removing **carbon dioxide** (CO₂), for example through natural carbon sinks and using carbon-removal technologies. On its way to the 2050 target, the EU has committed itself to reducing net GHG emissions by at least 55 % by 2030 compared with 1990 levels.

GHG emissions continue to fall compared with pre-pandemic levels, with more to be done to meet the 2030 target

Estimates for net GHG emissions, which include net removals from land use and forestry, suggest that the EU achieved close to a 30 % reduction between 1990 and 2021 ⁽¹⁾. This means that over the next nine years, emissions will need to fall much quicker if the EU wants to reach its net GHG emission reduction target of 55 % by 2030.

A large proportion of the EU's emission reductions since 1990 have occurred between 2006 and 2021, with net emissions falling by 23.0 % during this period. The short-term trend has been less clear-cut, experiencing both ups and downs. Net GHG emissions increased slightly between 2014 and 2017, but fell again between 2017 and 2020. A remarkable 10.6 % drop occurred in 2020,

The EU reduced its net GHG emissions by 8.9% between 2016 and 2021

which can mainly be attributed to the measures taken in response to the COVID-19 pandemic and the related reduction in energy consumption. However, net GHG emissions partially bounced back in 2021, with an increase of 6.0 % compared with 2020. Overall, EU net emissions fell by 8.9 % between 2016 and 2021. GHG emission estimates for the first three quarters of 2022 suggest that GHG emissions have remained below pre-pandemic levels ⁽²⁾. However, there is still uncertainty around the impacts of Russia's invasion of Ukraine and the resulting energy crisis on the EU's GHG emissions (see also the chapter on SDG 7 'Affordable and clean energy' on page 133).

Per capita emissions have fallen in line with the overall reduction in net GHG emissions

Across the EU, net GHG emissions per capita ranged from 0.9 to 16.9 tonnes of CO₂-equivalent in 2021. Luxembourg by far exceeded the per capita emissions of other Member States, which can be partly attributed to a considerably higher number of commuters and transit traffic ⁽³⁾. Compared with 2016, net GHG emissions per capita have fallen in all but seven Member States. Latvia reported the strongest increase in net emissions per capita, of 41.7 %, mainly as a result of reduced carbon removal by forest land. Finland and Lithuania also saw a rise in net emissions of more than 10 % between 2016 and 2021. Sweden reported the strongest reduction among Member States, of 50.0 %, followed by Slovenia with 28.9 % ⁽⁴⁾.

The average carbon footprint, which refers to CO₂ emissions from consumption, differs significantly between people according to their incomes. Data from the World Inequality Database ⁽⁵⁾ show that in 2020 the carbon footprint of the richest 10 % of the EU population was five times higher than for the poorest 50 %. This inequality was lowest in Malta (3.9 times) and the Netherlands (4.0) and highest in Luxembourg (7.1), Romania (6.5) and Austria (6.3).

Carbon removals remain on a downward trend

Net GHG removals come from land use and forestry, which is also referred to as the 'land use, land use change and forestry (LULUCF)' sector according to the Intergovernmental Panel on Climate Change (IPCC) classification. Within this sector, forests remove CO₂ from the air (as trees capture CO₂ through photosynthesis), which usually overcompensates for emissions from land use (for example, from the use of fertilisers) and land use change (for example, when grassland is converted to cropland).

In the EU, GHG net removals from land use and forestry fell by 0.6% between 1990 and 2021. While carbon removals from forest land increased in the first half of the period, the trend reversed between 2006 and 2021, with net removals from all land types falling by 36.4%. The largest decrease happened over the last five years of this period, when net removals fell by 28.7%. Due to the large drop in total GHG emissions, net removals still compensated for 6.0% of emissions in 2021, even though this is a lower share compared with previous years. In absolute numbers, net removals amounted to 211.8 Mt of CO₂-equivalent in 2021. This is well below the EU's [net carbon removal target for land use and forestry](#) of at least 310 Mt of CO₂-equivalent by 2030.

Net carbon removal from land use and forestry in the EU in 2021 amounted to 211.8 Mt CO₂-eq

Emissions associated with energy consumption have fallen thanks to reduced energy consumption and increased use of renewables

A sectoral breakdown of the years 1990 and 2021 shows that all sectors of the economy reduced their GHG emissions over this period, except transport ⁽⁶⁾. Fuel combustion in energy industries — which covers electricity and central heat generation — showed the strongest reduction. This was due to a general drop in

energy consumption and an increasing share of renewable energy sources, which reached 37.5% of electricity consumption in 2021. As a result of these developments, fuel combustion by energy users (excluding transport) replaced energy industries as the largest emission source in 2020 and remained the top emitting sector with 27.4% of total GHG emissions in 2021. Driving this rise in fuel combustion by energy users was a 2.3% increase in fossil fuel consumption in buildings between 2016 and 2021, despite the share of renewables in heating and cooling growing by 2.5 percentage points over the same period, to reach 22.9% in 2021. Transport emissions dropped by 8.9% between 2016 and 2021, following a reduction in fossil fuel use alongside an increase in consumption of renewable fuels ⁽⁷⁾. In total, renewable energy contributed 21.8% of the EU's gross final energy consumption in 2021. While this was an increase of 3.8 percentage points between 2016 and 2021, stronger progress seems necessary to reach a 42.5% share of renewable sources in energy consumption by 2030.

21.8% of energy consumed in the EU in 2021 came from renewable sources

Average CO₂ emissions per km from new car fleets have fallen over the past decade

Passenger cars are responsible for a considerable share of the EU's total GHG emissions. To reduce those emissions, the EU has set targets for the fleet-wide average emissions of new passenger cars. For each manufacturer's new car fleet, a binding specific emission target has been set based on the average mass of its new vehicles so that the overall target for the EU's average fleet emissions will be met.

Between 2007 and 2020, data on the average CO₂ emissions per km from new passenger cars were collected based on the New European Driving Cycle (NEDC) procedure. In 2021, the data collection method was changed to the World Harmonised Light-vehicle Test Procedure (WLTP), which is more representative of a vehicle's on-road emissions and leads to higher emission values

than the NEDC. To ensure manufacturers' targets are as equally stringent, these have also been converted to values based on the WLTP.

Data collected according to NEDC show that the average CO₂ emissions per km from new passenger cars registered in the EU fell almost continuously between 2007 and 2020, reaching 107.9 g/km in 2020, which is a 9.4% reduction since 2015. The new data collected according to WLTP show average CO₂ emissions per km from new passenger cars were 116.3 g/km in 2021.

116.3
grams of CO₂
per km
were emitted on
average by new
passenger cars
in the EU in 2021

Climate impacts and adaptation

Rising concentrations of CO₂ emissions and other GHGs lead to global warming and increased ocean acidity. As a consequence of global anthropogenic GHG emissions, the decade 2012 to 2021 was the warmest on record, with a global mean near-surface temperature increase of 1.11–1.14 °C compared with the pre-industrial level. This means that more than half of the warming towards the global 2 °C limit stipulated in the Paris Agreement has already occurred. The average annual temperature over the European continent has increased by even more, by 1.94–1.99 °C during this decade ⁽⁸⁾.

Climate impacts are a consequence of rising temperatures and the related intensity and quantity of extreme events which affect environmental, social and economic systems. The EU's SDG monitoring focuses on the economic costs that arise from weather- and climate-related extreme events. To minimise the impacts, countries are taking action to adapt to climate change by introducing measures such as flood protection, adapted agricultural practices and forest management, and sustainable urban drainage systems. Climate adaptation is also fully integrated into the Covenant of Mayors initiative, which covers thousands of cities in Europe and worldwide with the aim of mobilising local governments and regions to make voluntary but

ambitious climate mitigation and adaptation commitments.

Economic losses from weather- and climate-related extreme events have been considerable in recent decades

Studies have shown that various weather- and climate-related extreme events in Europe and beyond have become more severe and frequent as a result of global climate change ⁽⁹⁾. The resulting impact on human systems and ecosystems has led to measurable losses to economies and people's livelihoods ⁽¹⁰⁾. Reported economic losses generally reflect monetised direct damages to certain assets and as such are only partial estimates of the full damages. They do not consider losses related to mortality and health, cultural heritage or ecosystems services, which would considerably raise the estimate ⁽¹¹⁾.

Over the period 1980 to 2021, weather- and climate-related losses accounted for a total of EUR 559.8 billion. 2021 marked a new negative record, with climate-related economic losses amounting to EUR 56.6 billion in that year, most of which (EUR 43.2 billion) was caused by hydrological events. However, recorded losses vary substantially over time: about 57% of the total losses have been caused by just 5% of unique extreme events ⁽¹²⁾. This variability makes the analysis of historical trends difficult. However, a closer look at a 30-year moving average shows an almost steady increase in annual climate-related economic losses, from EUR 11.1 billion in 2009 to EUR 15.2 billion in 2021 ⁽¹³⁾, which corresponds to a 36.5% increase. The most expensive extreme climate events during the period from 1980 to 2021 included the 1999 storm Lothar and the 2000 flood in France and Italy, the 2002 flood in central Europe, and the severe floods in Germany, Netherlands, Belgium and Luxembourg in July 2021.

Over the period
1980 to 2021,

climate-related
economic
losses in the EU
accumulated to
EUR 559.8
billion

A growing number of local governments are committed to act on climate protection and adaptation

Communities play a vital role in implementing climate mitigation and adaptation actions on the grounds. In this context, the EU supports the [Covenant of Mayors for Climate and Energy](#), which was established in 2008 and is one of the EU's flagship climate initiatives. The Covenant of Mayors mobilises local governments and regions to make voluntary but ambitious climate commitments that help achieve emission reductions in and outside the EU and increase resilience to climate impacts. While initially focusing on mitigation measures only, from 2015 onwards the Covenant of Mayors for Climate and Energy has explicitly concentrated on mitigation and adaptation measures ⁽¹⁴⁾.

In 2022, Covenant of Mayors (CoM) signatories covered 196 million people in the EU, representing about 44 % of the EU population. Since 2010, the population covered by CoM signatories has grown almost steadily. In 13 EU Member States, CoM signatories represented more than half of the population in 2022. The highest share was reported by Belgium, with almost 95 % of the population, followed by Spain and Italy with slightly above 75 % each.

In parallel, by 7 March 2023, 284 regions and local authorities from EU countries (301 with Horizon partner countries also included) had signed up to participate in the [Horizon Europe Mission on Adaptation to Climate Change](#). The Mission will help these regions and local authorities to better understand, prepare for and manage climate risks, as well as to develop innovative solutions to build resilience.

Financing climate action

As part of the transition towards climate neutrality, the EU is endeavouring to redirect public and

private investments to areas where they will support this objective. For this reason, the EU has adopted the [EU taxonomy](#) as a classification system for sustainable economic activities and a [European green bond standard](#) as a voluntary 'gold' standard for the green bond market. At EU level, climate change mitigation and adaptation has been integrated into all major spending programmes ⁽¹⁵⁾ and the EU has also committed to support international climate action.

The EU's contribution to climate finance for developing countries has been increasing since 2014

In addition to investing in climate action within its borders, the EU and its Member States have committed to raising money to combat climate change and to adapt to climate impacts in developing countries. They are taking part in a commitment made by the world's developed countries to jointly mobilise USD 100 billion per year by 2025 from a wide variety of sources, instruments and channels ⁽¹⁶⁾.

Total EU public finance contributions (including all 27 Member States as well as the EU institutions) increased from about EUR 12.9 billion in 2014 to EUR 23.4 billion in 2020. In 2021, the contribution amounted to EUR 23.0 billion. The two largest contributors in the period were Germany and France. The European Investment Bank (EIB) and the European Commission were the third and fourth largest donors in 2021, respectively. In 2020, the EU, its Member States and the EIB together were the biggest contributors of public climate finance to developing countries worldwide ⁽¹⁷⁾. It is important to note that due to a methodological change, data since 2020 are not directly comparable with earlier years as recent data are based on commitments only, for both bilateral and multilateral finance.

Conserve and sustainably use the oceans, seas and marine resources for sustainable development

SDG 14 aims to protect and ensure the sustainable use of oceans. This includes reducing marine pollution and ocean acidification, ending overfishing and conserving marine and coastal ecosystems. SDG 14 is strongly related to other SDGs as oceans sustain coastal economies and livelihoods, contribute to food production and function as a carbon sink.

The livelihoods and well-being of Europeans depend heavily on the health and productivity of marine ecosystems. At the same time, the marine and coastal environments are affected by climate change, habitat alteration, biodiversity loss, over-exploitation of marine resources and pollution from various sources. Monitoring SDG 14 within the EU context thus involves looking into trends in the areas of ocean health, marine conservation and sustainable fisheries. The EU has made moderate progress towards SDG 14 over the assessed five-year period. On the positive side, marine protected areas have increased and fish stocks in EU marine waters (especially in the North-East Atlantic) seem to be recovering due to reduced fishing pressure. However, unsustainable trends are visible in the areas of ocean acidification (as a result of carbon dioxide emissions from human activities) and eutrophication.

Policy context

Ocean health and marine conservation

The [Marine Strategy Framework Directive \(MSFD\)](#) aims to ensure EU marine waters achieve good environmental status. The MSFD also promotes the establishment of marine protected areas, which, according to the [Maritime Spatial Planning Directive \(MSPD\)](#), have to be considered in maritime spatial planning.

The [Water Framework Directive](#) requires Member States to draw up management plans to ensure good ecological status of coastal waters. The [EU Bathing Water Directive](#) lays down provisions for monitoring bathing water quality at designated bathing sites.

The [UN Biodiversity Conference \(COP 15\)](#) in 2022 adopted a global biodiversity framework to protect at least 30% of the global sea areas by 2030. This goal was taken up by the landmark [Treaty of the High Seas to protect the ocean](#).

The [EU Biodiversity Strategy for 2030](#) aims to enhance the protection of marine ecosystems with the objective of achieving good environmental status. At the same time, the Commission's [proposal for a Nature Restoration Law](#) aims to restore European habitats in poor condition, including marine ecosystems.

The [Habitats Directive](#) contributes to the conservation of marine habitat types and species. The [Birds Directive](#) lists bird species that depend on marine habitats.

Making ocean sustainability a reality by 2030 is one of the four pillars of the EU's updated [International Ocean Governance Agenda](#).

To tackle marine pollution, the EU uses a wide set of legal instruments, including the regulations on [waste management and prevention](#), [port reception facilities](#) for ship-generated waste and cargo residues and the [Directive on Single Use Plastics](#).

The [Zero Pollution Action Plan for Air, Water and Soil](#) sets out key actions to improve water quality by reducing emissions of waste, plastic litter at sea and microplastics.

The [EU's new approach for a sustainable blue economy](#) fosters activities that preserve marine ecosystems, reduce pollution and increase resilience to climate change.

The [International Convention for the Prevention of Pollution from Ships \(MARPOL\)](#) aims to protect oceans and seas against pollution caused by maritime transport.

The [EU strategy on adaptation to climate change](#) aims to stop ocean acidification and encourage nature-based solutions for sustaining Europe's seas.

Sustainable fisheries

The [Common Fisheries Policy \(CFP\)](#) aims to ensure the long-term sustainability of the sector by ensuring the highest sustainable yield and conserving marine resources.

The [Action plan on protecting and restoring marine ecosystems for sustainable and resilient fisheries](#) contributes to the delivery of the EU Biodiversity Strategy for 2030.

The updated [EU Arctic policy](#) stresses the utmost importance of conserving and sustainably using Arctic marine living resources, including fish stocks.

Life below water in the EU: overview and key trends

Ocean health

Accomplishing the goal of clean, healthy and productive oceans requires an integrated approach that addresses different pressures. To monitor SDG 14 in the EU context, indicators have been chosen that focus on ocean acidification, eutrophication and bathing water quality. The EU is committed to improving water quality in marine waters and coastal areas in the sea basins around the EU. It aims to do this through a range of land-based and marine policies, and by active engagement in Regional Sea Conventions, the EU sea-basin and macro-regional strategies, and support to its outermost regions. As a result, some positive trends have been emerging for bathing water quality and the reduction of point-source pollution through improved waste water treatment. Oceans, however, have continued to acidify as a result of global climate change.

Seawater acidification poses a risk to the marine environment and global climate regulation

Seawater acidification occurs when increased levels of carbon dioxide (CO₂) in the atmosphere are absorbed by the sea. Acidification reduces calcification and affects biochemical processes such as photosynthesis, with knock-on effects for entire ecosystems ⁽¹⁾. Because cold water absorbs more CO₂, polar regions are disproportionately hard hit by acidification. Research has shown that organisms relying on calcification (for example, mussels, corals and plankton) and photosynthesis (plankton and algae) are particularly vulnerable to increased acidity ⁽²⁾.

In 2021, the mean pH level of global ocean surface water reached a new low of **8.049**

Before industrialisation, pH levels varied between 8.3 and 8.2. Since 1985, these levels have been declining at a steady rate, with the global mean surface seawater pH reaching an unprecedented low of 8.049 in 2021. EU leadership to mitigate climate change (see SDG 13) is thus of vital importance for reaching the SDG target 14.3 on minimising seawater acidification.

Pollution continues to threaten the marine environment

In addition to acidification, Europe's marine ecosystem remains at threat from organic and chemical pollutants from human activities, as well as marine litter and noise pollution. Excessive nutrient loads from agriculture and municipal [waste water](#) — in particular compounds of phosphorus and nitrogen — cause eutrophication, which can lead to problematic algal blooms and oxygen depletion with severe consequences for the marine ecosystem health and biodiversity.

The [Copernicus Marine Service](#) monitors all EU sea basins for oxygen depletion and measures anomalies in chlorophyll-a levels as an indicator of eutrophication. The chlorophyll data show strong annual fluctuations in the area of EU marine waters affected. For most of the years in the time series from 2000 to 2022, less than 20 000 square kilometres (km²) were affected, corresponding to less than 0.4% of the EU's exclusive economic zone (EEZ). However, in some years — for example 2007, 2008, 2018 and 2022 — more than twice that area was affected, highlighting strong annual variability. In 2022, 54 920 km² of EU marine waters were affected by eutrophication, corresponding to

1.0% of marine waters in the EU's exclusive economic zones were classified as eutrophic in **2022**

1.0% of the EU's EEZ. Using a smoothed four-year moving average to allow a clearer trend assessment confirms that over the five-year period assessed, from 2017 to 2022, the area affected by eutrophication was on the rise in the EU.

Another threat to the marine environment is chemical pollution from hazardous substances and marine plastic litter and microplastics. Chemical pollution stems from a number of land-based and marine sources, including agriculture (through the application of pesticides and veterinary medicines), industry, households and the transport sector. Of particular concern are persistent organic pollutants (POPs), which degrade slowly and can bioaccumulate in the food chain. Marine litter, such as plastic bottles and packaging, can also break down into smaller particles through photodegradation, releasing chemicals such as bisphenol A (BPA) and phthalates into the water. All in all, the transfer of toxic chemicals from the litter into the food chain is already taking place at large scale and may ultimately have combined effects on marine life and human health.

Estimates of plastic litter entering Europe's oceans are highly tentative, due to a lack of data. However, the [European Commission estimates](#) that 150 000 to 500 000 tonnes of plastic enter the EU's marine waters every year. Plastic pollution has many harmful effects on the marine environment, for example it may trap or strangle marine animals or be ingested by them. Marine plastic can come from both land- and sea-based sources. Single-use plastics account for about 50% of all marine litter on European beaches ⁽³⁾. Based on a Commission initiative, in 2019 the European Parliament and the Council adopted the new European [Directive on Single Use Plastics](#) targeting these plastics and fishing gear alongside other plastic products.

Human-induced eutrophication, contaminant concentrations, marine litter and noise pollution are common multiple pressures that must be minimised for marine waters to achieve good environmental status under the Marine Strategy Framework Directive (MSFD) and good ecological status for coastal waters under the Water Framework Directive (WFD).

European coasts offer an increasing number of bathing sites with excellent water quality

Coastal water quality is affected by land-based pollution from sewage, agriculture run-off, and surface run-off from coastal cities, which can carry hazardous chemicals, nutrients, and plastic litter and microplastics. The resulting pollution exerts significant pressure on aquatic ecosystems and underwater life.

In the EU, recent developments have been quite favourable in this regard, and as a result the water quality of the EU's coastal bathing sites has improved almost continuously since 2011.

The most important factors affecting the quality of these waters are microbiological contamination and marine litter. Between 2011 and 2021, the share of European coastal bathing sites with 'excellent' water quality grew more or less steadily, reaching 88.3% in 2021. It should be noted though that the bathing water indicator provides only a limited view of pollution in European seas because it is focused on the shore and excludes transitional waters or waters further away from the coast ⁽⁴⁾. In addition, because the classification of bathing water quality considers datasets reported for the past four bathing seasons, this indicator does not tend to fluctuate greatly from year to year.

quality in 2021

Marine conservation

The lives of European citizens depend in many ways on the services marine [ecosystems](#) provide, including climate regulation, fish and seafood provision, coastal protection, cultural value, recreation and [tourism](#). Against this backdrop, the European Commission and Member States have taken multiple steps to combat the degradation of aquatic and coastal [habitats](#) and [biodiversity](#), which pose a serious threat to human livelihoods,

food security and climate stability ⁽⁶⁾. A crucial step has been the designation of a network of marine protected areas (MPAs) ⁽⁶⁾, in which some human activities are subject to stricter regulation. The degree of protection and hence the effectiveness of MPAs depends on the management plan regulating each protected area. Management measures may range from a total ban on fishing, mining or wind power generation, to a more moderate protection regime where economic activity is restricted, for example, allowing only certain types of fishing methods. However, many MPAs still lack comprehensive management plans or permit potentially harmful activities ⁽⁷⁾. One of the commitments taken by the international community at the [2022 One Ocean summit](#) and the UN COP15 on Biodiversity has been to designate new MPAs to achieve the goal of 30% of marine space under protection by 2030. This goal is also supported by the landmark [Treaty of the High Seas to protect the ocean of the high ambition coalition on Biodiversity Beyond National Jurisdiction \(BBNJ\)](#) and was already included it in the EU [Biodiversity Strategy for 2030](#). With the ambition to accelerate the implementation of SDG 14 globally, the EU [pledged 52 commitments worth up to EUR 7 billion](#) at the UN Ocean Conference in June 2022.

While the extent of marine protected areas has been growing in the EU, the conservation status of marine habitats and species remains unfavourable

A [report by the European Environment Agency \(EEA\)](#) revealed that a high proportion of marine species and habitats across Europe's seas are still in 'unfavourable conservation status' and that the marine ecosystem condition is generally not 'good'. One approach to protect the state of marine ecosystems is the designation of MPAs.

Between 2012 and 2021, the extent of marine protected areas grew considerably, from

216 742 km² to 611 550 km². Even though this means MPAs represented only 12.1 % of overall EU marine area in 2021, the EU is on track to meet its 30% target by 2030. Since 2016, MPA coverage has grown significantly in 12 out of the 22 EU Member states with a sea border. The largest relative improvements in MPA size were reported from France, Greece, Cyprus and Spain.

Although a positive development, growth in the extent of protected areas alone does not provide a good indication of how well species and habitats are being protected. In fact, the EU currently has no overview or assessment of how effective the management plans associated with designated MPAs in EU regional seas are. In a [special report on the marine environment](#), the European Court of Auditors concluded that EU MPAs provide limited protection in practice.

To gain a better picture on MPAs, information on their connectivity, status and the implementation of conservation measures is needed. The [Biodiversity Strategy for 2030](#) requires the Commission, in cooperation with Member States and the European Environment Agency (EEA), to advance criteria and guidelines for the identification and designation of new protected areas, as well as for coherent management planning. The European Commission adopted an [action plan for protecting and restoring marine ecosystems for sustainable and resilient fisheries](#). This action plan calls on the EU Member States to take measures for minimising the by-catch of sensitive species and for prohibiting mobile bottom fishing in MPAs, owing to their high impact on seabed species and habitats.

12.1 %

Sustainable fisheries

Besides pollution, the unsustainable use of living resources is the main threat to marine habitats and species in the EU. An ecosystem-based approach to managing Europe's fishing fleets is provided for under the EU's common fishing policy and is required for biodiversity conservation.

Governance of fisheries in EU waters mainly focuses on fair access and sustainable supply. The European Common Fisheries Policy (CFP) aims to

ensure that EU fisheries are managed sustainably by setting catch limits at the maximum sustainable yield. It limits the total amount of fish catches and controls who is allowed to fish how, when and where to prevent damage to vulnerable marine ecosystems and preserve fish stocks.

Thus, the CFP's ambition and implementation will directly affect whether SDG 14 is achieved, in particular the aim of ending overfishing, destructive and/or illegal, unreported and unregulated fishing practices, and subsidies that encourage these activities. In addition, unsustainable fisheries are a major threat to marine ecosystems through

the bycatch of non-target species (such as birds and cetaceans) and seabed degradation. The CFP empowers Member States and the Commission to regulate fisheries in a way that it is also compliant with the obligations of the Birds and Habitats Directives and the MSFD.

Improved sustainability of fisheries in EU marine waters

European fisheries affect fish stock productivity and stock size through catches. However, because stock size also varies naturally, the management of fisheries is a complex exercise. Controlling fishing mortality is one way of managing fisheries. Fishing mortality (F) reflects the proportion of fish of a given age that is caught by fisheries during one year. For fisheries to be sustainable, fishing mortality should not exceed the maximum sustainable yield value (F_{MSY}), which will provide the largest catch that can be taken from a fish stock over an indefinite period without harming it.

The model based median value of all F/F_{MSY} stock assessments can be used to estimate fishing pressures on fish stocks. Values above 1.0 mean the current fishing mortality exceeds the estimated maximum sustainable yield. The results for EU marine waters mirror the downward trend in overexploited overall stocks and show a 37 %

Between 2005 and 2020, fishing pressure in EU marine waters decreased by 37%

reduction in fishing pressure, from 1.87 in 2005 to 1.17 in 2020. However, this overall figure masks the fact that while fish stocks in the North-East Atlantic (including the Baltic Sea) — where about three-quarters of the EU's catch originates — were on average fished sustainably (F/F_{MSY} median of 0.76 in 2021), the Mediterranean and Black Sea fish stocks were still heavily overfished (F/F_{MSY} median of 1.71 in 2020). If the EU is to meet its own targets for sustainable fisheries, efforts need to be increased substantially in these sea regions.

At the same time, there has been an improvement in the number of stocks fished below F_{MSY} in the North-East Atlantic. In 2003, only 27 % of stocks in this region were fished below F_{MSY} , whereas in 2021, this figure had risen to 74 %⁽⁸⁾. In turn, however, this means that a quarter of North-East Atlantic stocks were still overfished.

The EU's approach to sustainable fisheries is not limited to respecting MSY . The Marine Strategy Framework Directive requires commercially exploited fish and shellfish populations to have a healthy distribution of age and size.

The status of stocks and their reproductive capacity can be measured and described by fish stock biomass as well as by spawning stock biomass (SSB). Biomass estimates are, however, associated with high levels of uncertainty due to the high annual variability of stock biomass. Fish stocks can also take time to respond to changes in management measures, and results can be masked by other factors, such as environmental conditions and predation⁽⁹⁾. For this reason, analyses of stock biomass trends should always focus on longer term patterns. There has been an estimated 22 % increase in biomass in EU marine waters between 2005 and 2020. The increase has been stronger in the North-East Atlantic, gaining about 43 %, while stock biomass only grew by only 3 % in the Mediterranean and Black Sea.

Between 2005 and 2020, fish stock biomass in EU marine waters increased by 22%

15

Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss

SDG 15 seeks to protect, restore and promote the conservation and sustainable use of terrestrial ecosystems. This includes efforts to sustainably manage forests and halt deforestation, combat desertification, restore degraded land and soil, halt biodiversity loss and protect threatened species.

SDG 15 is one of the key goals at international level that addresses biodiversity and ecosystems. In the EU, this goal ensures that the health and functioning of terrestrial ecosystems and the delivery of ecosystem services remain a priority, especially in the face of global trends such as population growth, accelerating urbanisation and an increasing need for natural resources. Monitoring SDG 15 in an EU context focuses on trends in ecosystem status, land degradation and biodiversity. The EU has on average slightly moved away from SDG 15 objectives over the past few years. While the EU's terrestrial protected areas and forest area have grown, recent trends for pollutant concentrations in EU rivers have been mixed. Indicators on species' biodiversity show a long-term and continued decline in common birds and grassland butterflies in the EU.

Policy context

The [EU Biodiversity Strategy for 2030](#) aims to put Europe's biodiversity on a path to recovery by 2030, by establishing a larger EU-wide network of protected areas on land and at sea, launching a nature restoration plan, and introducing measures to enable the necessary transformative change and to tackle the global biodiversity challenge.

The [Proposal for a Nature Restoration Law](#) from 2022 is a key element of the EU Biodiversity Strategy for 2030. It calls for legally binding targets to restore degraded ecosystems, in particular those that can best capture and store carbon as well as prevent and reduce the impact of natural disasters.

The [EU Birds Directive](#) and the [Habitats Directive](#) aim to maintain or restore a favourable conservation status of protected habitats and species, and safeguard their sustainable use and management. The Birds Directive protects all wild bird species and their habitats. The Habitats Directive introduces similar measures but extends its coverage to more than 1 300 other rare, threatened or endemic species of wild animals and plants. In addition, the Habitats Directives covers 233 natural habitat types.

The [EU Forest Strategy for 2030](#) aims to improve the quantity and quality of EU forests and strengthen their protection, restoration and resilience. It includes a roadmap outlining how to achieve the [3 billion additional trees commitment](#) in line with the ecological principles set out in the EU Biodiversity Strategy for 2030. A high proportion of forests are also covered in the Habitats Directive.

The [EU Soil Strategy for 2030](#) sets out a framework and concrete measures for protecting and restoring soils and ensuring they are used sustainably.

The [Water Framework Directive](#) imposes restrictions on activities that could pollute and damage Europe's freshwater resources. This legislation is complemented by the [EU Drinking Water Directive](#) and [Nitrates Directive](#), which also restrict levels of chemicals and minerals in Europe's freshwater resources.

The [LIFE Programme](#) is the EU's key funding instrument for environmental and nature conservation projects. It plays an important role in restoring and safeguarding the condition of terrestrial and freshwater ecosystems.

The [Zero Pollution Action Plan for Air, Water and Soil](#) maximises synergies with relevant EU policies, such as limiting soil sealing and urban sprawl.

Europe's [Common Agricultural Policy](#) (CAP) requires that utilised agricultural area covered by income support (under the system of conditionality) protects the climate and the environment, including water, soil and biodiversity of ecosystems. The CAP establishes a framework of standards that aim, among other things, to prevent soil erosion, protect biodiversity and landscape. Additional funding is available for farmers through the [European Agricultural Fund for Rural Development](#) to implement environmental and climate-related interventions, among other objectives aimed at protecting nature and safeguarding biodiversity.

The revised [EU Initiative on Pollinators](#) represents an integrated framework to tackle the causes of pollinator decline, improve knowledge and mobilise all actors across society.

Life on land in the EU: overview and key trends

Ecosystem status

Humans benefit greatly from many [ecosystem services](#), such as clean air, purified water and food provision. In addition, terrestrial ecosystems provide natural resources used in industrial processes and cultural services such as outdoor recreation. Other services that ecosystems offer include protection from natural disasters, such as flooding, and mitigation of the negative effects of [climate change](#). Human activities that degrade ecosystems, including pollution and the overuse of resources, threaten animals and plants and, as a result, the provision of ecosystem services and their benefits to human well-being ⁽¹⁾.

In 2019, the [Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services](#) (IPBES) released a [Global Assessment Report on Biodiversity and Ecosystem Services](#). The key findings of the report indicate that negative trends in biodiversity and ecosystem services are expected to hinder progress towards the Agenda 2030 and its SDGs. As such, current global conservation and sustainability goals will not be met unless transformative change is implemented. In 2021, the European Commission published the report [Accounting for ecosystems and their services in the European Union \(INCA\)](#), which delivered an integrated system of ecosystem accounts for the EU. The report's key findings suggest that between 2000 and 2018, changes in the extent of most ecosystem types were small in relative terms. However, urban ecosystems saw a significant increase in their extent, indicating a continued expansion of urbanised areas at the expense of semi-natural ecosystems and farmland. The report also suggests that sites in the Natura 2000 network tend to have a higher degree of ecosystem stability than those outside the network ⁽²⁾. Reacting to the negative biodiversity trends, the 15th meeting of the Conference of Parties to the UN Convention on Biological Diversity (CBD-COP15) in December 2022 agreed on the '[Kunming-Montreal Global Biodiversity Framework](#)' (GBF). The framework announced four long-term goals related to the 2050 Vision for

Biodiversity and included 23 global biodiversity targets to be achieved by 2030. It adopted a [global monitoring framework](#) to observe the implementation.

Some types of terrestrial ecosystems (for example, wetlands, heathlands and scrub) and the pressures placed on them (such as invasive species, habitat fragmentation, and noise and light pollution) are not monitored in this report due to data shortcomings. It is therefore important to recognise the limitations in presenting a full and complete picture of Europe's terrestrial ecosystems, the status of which cannot be fully assessed with the long-term datasets currently available.

Organic and phosphate pollution levels in EU rivers have been decreasing since 2000

The ecological status of European water bodies gives an important indication of how Europe's natural environment is faring in the face of pressures from human use. Two indicators monitor progress in this area: biochemical oxygen demand in rivers and phosphate in rivers. While these indicators paint a somewhat favourable picture of the EU's progress in making rivers cleaner over the past 20 years, the short-term developments have been less clear-cut.

Biochemical oxygen demand (BOD) in rivers is an indicator of organic water pollution and the effectiveness of water treatment. When a high level of oxygen (O₂) is required for the microbiological decomposition of organic compounds in water there is less O₂ available for other river species. As such, biochemical oxygen demand provides an indication of a river system's overall health. In 2020, the biochemical oxygen demand in EU rivers was 2.65 milligrams (mg) of O₂ per litre (L) of water, representing a 21.1 % reduction from 3.36 mg/L in 2000. Between 2015

In 2020, the biochemical oxygen demand in European rivers amounted to **2.65 mg/L**

and 2020, 11 out of 16 reporting Member States saw reductions in BOD in their rivers, with the EU's levels falling by 12.8% over this period.

Phosphate (PO_4) in rivers can originate from agricultural production, [urban waste water](#) and industrial discharges. Heavy loads of phosphate in rivers can harm the environment by causing biodiversity loss and water eutrophication. European phosphate concentrations have fallen by 17.2% since 2000, reaching 0.072 mg/L in 2020. Overall, this reduction can be linked to the introduction of measures by national and European legislation, such as the Urban Waste Water Treatment Directive ⁽³⁾ and a switch to phosphate-free detergents ⁽⁴⁾.

Declines in phosphate concentrations in EU rivers, however, levelled off in 2011 and have even increased slightly in recent years. Between 2015 and 2020, phosphate concentrations in EU rivers increased by 24.1%. This tendency may be related to slower reductions in phosphorus emissions from the agricultural sector ⁽⁵⁾ and a rise in phosphorus fertiliser consumption since 2010 in some Member States ⁽⁶⁾. Of all the reporting Member States, rivers in Finland and Sweden on average had the lowest concentrations of phosphate between 2015 and 2020. This is likely to be a result of their low population densities and high levels of waste water collection and treatment. In contrast, relatively high concentrations were found in some Member States with high population densities and/or intensive agriculture. The high and increasing short-term values observed, particularly in Bulgaria, Belgium and Lithuania, may lead to freshwater eutrophication ⁽⁷⁾.

The share of forest area in the EU is growing

Europe's [forests](#) provide multiple benefits, such as enhancing soil fertility and conserving soil moisture, storing carbon and providing habitats for animals and plants. They also provide employment in rural areas and help mitigate

climate change and regulate the microclimate. In 2018, forests and other wooded land covered 43.5% of the EU's total area. As a proportion of total land area, the EU's share of forests and other wooded land increased slightly, by 0.9 percentage points, between 2015 and 2018.

Currently, forests are affected by pressures from habitat degradation and loss, invasive alien species, pollutants and excessive nutrient loads, as well as climate change ⁽⁸⁾, which has resulted in persistent droughts and heatwaves. This means that EU efforts to retain and sustainably manage its forested areas are increasingly important. According to the latest assessment of the [State of Nature in the EU](#), only around 14% of forest habitats at the EU level are in good conservation status, while the rest are in poor and bad conservation status. Nevertheless, the report shows that forest habitats have experienced the most improvement compared with other habitats.

43.5%
of the EU area
was covered by
forest and other
wooded land in
2018

Land degradation

Land degradation is linked to the long-term functionality and biological productivity of land or land-based ecosystems. It is a complex phenomenon bringing together several elements, including soil degradation and the capacity of land to support water resources, biodiversity and primary productivity ⁽⁹⁾. Soil degradation by itself covers many aspects such as soil sealing and contamination, erosion by wind and water, loss of soil biodiversity, compaction, decline in organic matter, desertification, acidification and salination ⁽¹⁰⁾. Not all of these threats to soil quality can be covered in this indicator set, so the analysis has been limited to changes in imperviousness and soil erosion by water.

Land take is continuing to increase in the EU

Land take is described as the process of transforming agricultural, forest and other semi-natural and natural areas into artificial areas. It

often means an increase in settlement area over time, usually at the expense of agricultural areas. Land take can be monitored using the [Copernicus CORINE land cover datasets](#), which have been published every six years since 2000. Net land take includes the 'reverse land take process', which occurs when artificial areas are returned to non-artificial land categories through recultivation and renaturalisation. According to [data from the European Environment Agency \(EEA\)](#), net land take in the EU amounted to 11 845 square kilometres (km²) between 2000 and 2018, equalling an average annual net land take of 658 km². Even though the rate of net land take has fallen by more than 40% over the three observation periods, there is still a long way to go to meet the 'no net land take' policy target for 2050.

In 2018, the area of sealed soil surface in the EU was 1.8%

Soil sealing is the most intense form of land take and is essentially an irreversible process. It destroys or covers soils with layers of partly or completely impermeable artificial material such as asphalt and concrete ⁽¹¹⁾. Increases in the area of sealed land can be used to estimate land-use change for human use or intensification. The area of sealed soil in the EU has increased in all Member States since 2006. Between 2006 and 2015, the total area covered with impervious materials grew by 2 983 km² or 4.5%. Between 2015 and 2018, it increased by 3.7%. A substantial but unknown share of the increase is due to improvements in methodology and spatial resolution of the underlying remote-sensing data. According to the newest methodology, 1.8% of the EU was covered with impervious materials in 2018.

In all three observation periods, [EEA data](#) show that agricultural areas were the most likely to be converted to artificial surfaces, reducing the amount of land available for food and feed production. This results in increased fragmentation and loss of natural habitats. Furthermore, artificial areas create plots that are isolated from functional ecosystems and can lead to increased flood risk and more frequent rapid surface runoff ⁽¹²⁾. Moreover, sealed lands cannot store carbon and

thereby contribute to greenhouse gas emissions and climate change.

Fewer areas in the EU are now at risk of severe soil erosion by water

Soil is a resource that provides multiple benefits to society, including the provision of raw materials, food production, storage, filtration and the transformation of many substances, including water, carbon and nitrogen. Maintaining soil health ensures the continued provision of these benefits. While soil erosion by water poses the biggest threat to EU soils, multiple erosion processes, including water, tillage, wind and crop harvesting erosion contribute to soil degradation simultaneously or subsequently. Co-occurring processes may enhance and trigger each other or lead to self-reinforcing feedback loops, and thus enhance the severity of soil degradation ⁽¹³⁾.

Severe soil erosion by water is estimated to affect more than 5% of the non-artificial erodible land area in the EU and is responsible for 52% of total soil loss in Europe ⁽¹⁴⁾. Overall, water erosion is the major cause of soil displacement, both quantitatively (51% of the total displacement) and spatially (57% of the total area). Tillage erosion is in second place (36%), followed by wind erosion (10%) and crop harvesting (2.7%) ⁽¹⁵⁾.

There are hotspots in some European regions, in particular in the Mediterranean and continental areas, mainly due to a combination of steep topography and high rainfall erosivity ⁽¹⁶⁾. Modelling results up to 2070 show that water erosion could rise by up to two-thirds compared with today ⁽¹⁷⁾. In addition, there are other erosion processes that can be attributed to about 40% of the soil displacement in EU arable landscapes. Because of their ephemeral nature, these processes often occur almost unnoticed without leaving substantial geomorphic evidence but may act as a trigger and enhance soil degradation. Accordingly, new evidence suggests that countries

Between 2010 and 2016, the estimated land area at risk of severe soil erosion by water in the EU fell by 0.9%

such as Denmark and the Netherlands, which are generally considered to be little affected by soil erosion, are very prone to wind erosion risks ⁽¹⁸⁾.

However, efforts to address and mitigate soil erosion by water have helped to reduce the estimated EU land area at risk of severe soil erosion (soil loss of more than 10 tonnes per hectare per year) by water, from 198 607 km² in 2010 to 196 853 km² in 2016, equalling a decrease of 0.9%. This represents a considerable slowdown compared with the period 2000 to 2010, when the estimated area at risk fell by 12.6%.

Between 2010 and 2016, arable land experienced the greatest reduction in area at risk of soil erosion compared with other land types ⁽¹⁹⁾. Here, improvements due to the implementation of agro-environmental standards under the Common Agricultural Policy (CAP) may have helped to reduce the mean rate of soil loss by water erosion. This includes the application of soil conservation practices such as reduced tillage, preservation of a minimum soil cover, reduction in the area of bare soils, contour farming along slopes, maintenance of terraces and stone walls, and extended use of grass margins ⁽²⁰⁾.

Biodiversity

Terrestrial ecosystems have been protected under the Birds Directive since 1979 and the EU Habitats Directive since 1992. Both Directives form the main pillar for the protection of Europe's biodiversity and ecosystems. Under these Directives, Member States are required to designate and manage Special Protection Areas (SPAs; Birds Directive) and Sites of Community Importance/Special Areas of Conservation (SCIs/SACs; Habitats Directive). These sites, collectively known as the Natura 2000 network, should enable protected habitats and species to reach favourable conservation status in the EU. The Natura 2000 network is complemented by nationally designated terrestrial protected areas that are established under each Member State's national framework. The [EU Biodiversity Strategy for 2030](#) includes a target for at least 30% of EU land to be protected.

Despite an increase in protected areas, many terrestrial habitats and species in the EU have not reached 'favourable conservation status'

In 2021, the EU and its Member States protected 1 074 254 km² of terrestrial habitats, covering 26.0% of the EU's land area. This is an increase of almost 35% compared with 2013, when only 798 550 km², equalling 18.9% of the EU's area, were protected. Even though the designation of new protected areas has slowed in recent years, the EU appears to be on track to meet its 30% target by 2030 if it can maintain the pace observed between 2016 and 2021. The Member States with the largest protected areas relative to country size in 2021 included Luxembourg (55.8%), Bulgaria (41.0%) and Slovenia (40.5%). In contrast, the shares of protected areas were smallest in Finland (13.3%) and Ireland (13.9%).

The latest assessment of the [State of Nature in the EU](#) reveals that many species and habitats of European interest are still in unfavourable conservation status. The conservation status of habitats did not improve over the reporting period (2013–2018), but for species other than birds a slight improvement can be stated. Across the EU, about a quarter (27%) of species assessments and 15% of the habitat assessments show a good conservation status, compared with 23% and 16%, respectively, reported in the [assessment from 2015](#). The majority of the assessments considered, however, have a poor or bad conservation status at EU level (63% for species and 81% for habitats). Moreover, a look at the trends reveals that only 6% of species assessments and 9% of habitat assessments showed improving trends in the reporting period, while 35% and 36% indicated a deteriorating trend at EU level, respectively.

The State of Nature report also shows that fish and molluscs continue to have a particularly high proportion of species (around 30% each) with a bad conservation status, while reptiles

and vascular plant species have the highest proportion of good conservation status (36 % and 40 % respectively). Habitats in dunes, bogs, mires and fens have the highest share of assessments showing a bad conservation status (around 50 % each). Grasslands, which contain some species-rich habitats that are particularly suitable for pollinator species, also have one of the highest proportions of bad conservation status assessments (49 %).

Common birds and grassland butterflies are in long-term decline in the EU

Changes in land use and overuse of ecosystems can harm biodiversity. Because biodiversity supports all ecosystem functions and contributes to their capacity to provide ecosystem services ⁽²¹⁾, it needs to be monitored so it can be preserved and restored. Birds are sensitive to both human-induced and natural environmental change, making them good indicators of wider ecosystem health. Their widespread and diverse habitats also make them ideal for monitoring the results of conservation efforts.

The EU [common bird index](#) tracks the population abundance and diversity of a selection of common bird species in the EU, further typified by common forest and common farmland bird species. The index shows an 11.8 % decline of common birds and a dramatic 35.9 % fall in the abundance of common farmland birds between 1990 and 2021. Common forest birds have declined slightly, with their index falling 4.7 % over the whole period. The decline in common farmland birds has largely been attributed to agricultural intensification, which has reduced natural nesting habitats such as hedges, wetlands, meadows and fallow fields. Agro-chemicals, such as pesticides, and changes in ploughing times for cereals have also affected common farmland birds, disrupting breeding and reducing available food sources, in particular insect populations ⁽²²⁾. Shorter-term trends show a continued decline for all common birds and common farmland bird populations. For

Between 2006 and 2021, common bird populations in the EU declined by 6.8%

all common birds there has been a 6.8 % decline since 2006 and a 2.2 % decline since 2016, while common farmland birds continued to show an even stronger decline, by 20.2 % since 2006 and 7.8 % since 2016.

Butterflies, which are among the most common plant pollinators, are well suited to acting as signals of environmental and habitat health. They occur in a wide range of habitat types and are sensitive to environmental change. The [SPRING](#) (Strengthening Pollinator Recovery through INdicators and monitorinG) and [ABLE](#) (Assessing Butterflies in Europe) projects have generated a butterfly indicator for widespread species of grassland butterflies.

The grassland butterfly index is based on data from 18 Member States, measuring the population trends of 17 butterfly species within the national Butterfly Monitoring Schemes ⁽²³⁾. According to estimates from these monitoring efforts, butterfly populations declined by 29.5 % between 1991 and 2020, signifying a dramatic loss of grassland biodiversity. While moderate climate warming aided a temporary increase in butterfly populations between 2002 and 2012, the increasing frequency of extreme temperatures led to even stronger declines in the subsequent years ⁽²⁴⁾. Overall, grassland butterfly populations thus fell by 24.3 % between 2005 and 2020, and by 28.9 % between 2015 and 2020. The main causes for this decline can be attributed to land use changes in rural areas, in particular stemming from intensification of agricultural grasslands, and deposition of nitrogen in protected areas, mainly in north-western Europe. In the rest of Europe, grassland abandonment is a threat ⁽²⁵⁾. Butterflies show a decline in non-urban areas but they have been stable within urban areas across Europe, suggesting that parks and other green parts of the urban environment are becoming increasingly suitable and are being managed in a butterfly-friendly way. However, the situation of butterflies in urban areas requires further research, as different studies offer contrasting findings ⁽²⁶⁾.

Between 2005 and 2020, grassland butterfly populations in Europe shrank by 24.3%

16

Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels

SDG 16 calls for peaceful and inclusive societies based on respect for human rights, protection of the most vulnerable, the rule of law and good governance at all levels. It also envisions transparent, effective and accountable institutions.

Peace and security are a prerequisite for sustainable development, in line with the integrated nature of the 2030 Agenda. Peace, security, democracy, the rule of law and respect for fundamental rights are also founding values of the EU. Monitoring SDG 16 in an EU context focuses on personal security, access to justice and trust in institutions within the EU. Over the past few years, the EU has become a safer and more just place to live, as deaths due to homicide or assault and perceived occurrence of crime, violence and vandalism have fallen considerably. Government expenditure on law courts has increased significantly and more than half of Europeans consider their justice system to be independent. The assessment of corruption in the EU has remained stable. However, challenges persist in some areas of access to justice and trust in the EU institutions has fluctuated over the past few years.

Policy context

Peace and personal security

In 2020, the European Commission set out a new [EU Security Union Strategy](#) for the period from 2020 to 2025. It maps out the main actions, tools and measures to ensure European security, both in the physical and digital worlds, and across all parts of society. The strategy identified three priorities: fighting organised crime and human trafficking, countering terrorism and radicalisation, and fighting cybercrime.

Access to justice

Improving the effectiveness of justice systems in Member States has been identified as a key component for structural reforms

in the [European Semester](#). With the help of the [EU justice scoreboard](#), the EU monitors the efficiency, quality and independence of Member States' justice systems.

Trust in institutions

With the adoption of the [Stockholm Programme](#), the Commission has been given a political mandate to measure efforts in the fight against corruption and to develop a comprehensive EU anti-corruption policy.

In EU legislation, the fight against corruption is covered by the [1997 Convention on fighting corruption involving officials of the EU or officials of Member States](#) and the [2003 Framework Decision on combating corruption in the private sector](#).

Peace, justice and strong institutions in the EU: overview and key trends

Peace and personal security

Safety is a crucial aspect of a person's life. Insecurity is a common source of fear and worry, and negatively affects quality of life. Physical insecurity includes all the external factors that could potentially put an individual's physical integrity in danger. Crime is one of the most obvious causes of insecurity. Analyses of physical insecurity usually combine two aspects: the subjective perception of insecurity and the objective lack of safety. Available time series on both objective and subjective measures of personal safety show a favourable trend in the EU over the past decade.

0.7
deaths per
100 000 people
in the EU in
2020 were
caused by
homicides

The EU has become a safer place to live

Homicide is one of the most serious crimes. In the EU, deaths due to homicide have fallen steadily since 2005, reaching a rate of 0.7 deaths per 100 000 people in 2020. This corresponds to a reduction of 45 % over the assessed 15-year period. In the short-term, however, the trend has stagnated, remaining at roughly the same level since 2016. The decrease in homicides in the EU has gone hand in hand with improvements in people's perception of crime, violence or vandalism. Since 2010, the share of people reporting the occurrence of such problems in their area has generally fallen in the EU. In 2020, 10.7 % of the population felt affected

10.7%
of the EU
population
reported crime,
violence or
vandalism in
their area in
2020

by these issues, which is 2.4 percentage points less than in 2010 and the lowest value recorded.

The perception of being affected by crime, violence or vandalism differs across socio-demographic subgroups of the EU population and across degrees of urbanisation. While 13.7 % of the population living in households with an [equivalised disposable income](#) below the poverty threshold — set at 60 % of the national median equivalised income — felt affected by such problems in 2020, this was only the case for 10.2 % of the population living in households above the poverty threshold. Similarly, in 2020 the perceived occurrence of crime, violence or vandalism in cities (16.3 %) was almost three times higher than in rural areas (5.8 %) and almost twice as high as in towns and suburbs (8.4 %) ⁽¹⁾.

The fear of victimisation paradox: when objective and subjective measures of physical insecurity do not match

National figures show that the perceived exposure to crime, violence or vandalism in 2020 was eight times higher in the most affected country (19.1 % of the population in Bulgaria) than in the least affected country (2.4 % in Croatia). However, country differences in this subjective indicator need to be treated with caution. Research suggests that crime rates from police registers and the subjective exposure to crime may differ, as population groups with low victimisation rates may be particularly afraid of crime (the so-called 'fear of victimisation paradox') ⁽²⁾. This is, for instance, the case in Ireland, which has the lowest death rate due to homicide across the EU, but one of the highest shares of people who say they feel affected by crime or other problems in their area (see Figures 16.2 and 16.4). In contrast, death rates due to homicide were the highest in the Baltic countries, which had rather low shares of people feeling affected by crime, violence or vandalism in their neighbourhood. It should, however, be acknowledged that this

comparison may not capture the full picture, as other forms of crime than homicide also contribute to perceived insecurity.

Men are more likely to die from homicide, while women are more likely to be victims of violence in their homes and sexual assaults

Deaths due to homicide in the EU show a remarkable [gender gap](#). While death rates due to homicide have fallen for both sexes, they remain about twice as high for men (0.9 deaths per 100 000 persons in 2020, compared with 0.4 deaths per 100 000 persons for women). However, while men have a higher overall risk of being killed, women have a significantly higher risk of being killed by their intimate partners or family members.

A study by the United Nations Office on Drugs and Crime (UNODC) and UN Women shows that intimate partner- or family-related homicides accounted for 56 % of women who were killed in 2021 globally, while this was only the case for 11 % of male homicides. Overall in Europe, according to an earlier UNODC report, almost a quarter (24 %) of homicides in 2017 (compared with 18 % globally) were at the hands of an intimate partner or were family-related ⁽³⁾. In 2021, 51 % of all femicides were partner- or family-related. Despite an overall decrease in female intimate partner and family-related homicides in Europe since 2010, the number increased in the first pandemic year (2020) in some parts of Europe, specifically in western Europe ⁽⁴⁾. This is an issue of concern, given that women are at a much higher risk of being killed by their partners or family members (globally, 64 % of victims of intimate partner/family-related homicide were women), and especially when considering the broader concept of violence against women, encompassing all forms of physical, sexual and psychological violence.

Data from Eurostat's official crime statistics on intentional homicide and sexual offences show that women are much more likely to be a victim of such crimes than men. In 2020, 49 out of 100 000 women were victims of sexual assault, and 28 out of 100 000 women were victims of rape. The rates were significantly lower for men, with 9 out of

100 000 experiencing sexual assault and 3 out of 100 000 having been victims of rape ⁽⁵⁾. Moreover, women are about twice as likely as men to be a victim of intentional homicide by family and relatives or their intimate partner. In 2020, 0.4 out of 100 000 women were victims of such homicide, compared with only 0.2 per 100 000 men ⁽⁶⁾.

The prevalence of violence varies greatly across the EU. However, cross-country comparisons of the crime statistics should be made with caution. Comparability is affected by different legal definitions concerning offenders and victims, different levels of police efficiency and the stigma associated with disclosing cases of violence against women ⁽⁷⁾ (see the chapter on SDG 5 'Gender equality' on page 103 for more information on gender-based violence).

Access to justice

Well-functioning justice systems are an important structural condition on which EU Member States base their sustainable growth and social stability policies. Whatever the model of the national justice system or the legal tradition in which it is anchored, quality, independence and efficiency are among the essential parameters of an 'effective justice system'. Because there is no single agreed way to measure the quality of justice systems, the budget actually spent on law courts is used here as a proxy for this topic. Moreover, judges need to be able to make decisions without interference or pressure from governments, politicians or economic actors, to ensure that individuals and businesses can fully enjoy their rights. The perceived independence of the justice system is used to monitor this aspect.

EU expenditure on law courts has grown over the past few years

In the EU, general government expenditure on law courts has risen by 48.7 % since 2006, reaching EUR 47.9 billion in 2021. In per capita terms, this corresponds to a 44.8 % increase from EUR 73.9 per inhabitant in 2006 to EUR 107.0 per inhabitant in 2021. However, when viewed as a share of total government expenditure, spending on law courts remained stable at 0.7 % between 2006 and 2019.

In 2020 and 2021, the share decreased to 0.6 % of total expenditure, largely due to increases in other government expenditure to mitigate the economic and social impact of the COVID-19 pandemic. In relation to GDP, expenditure on law courts has also been stable since 2006, at 0.3 % of GDP ⁽⁸⁾. Interestingly, in 2020 seven Member States increased their expenditure on law courts in relation to their GDP, and only one country reduced it.

48 billion
Euro were spent by governments on law courts across the EU in 2021

Just above half of the EU population considers the justice system to be sufficiently independent

In 2022, 53 % of EU inhabitants rated the independence of the courts and judges in their country as 'very good' or 'fairly good', which is one percentage point lower than in 2017. At the same time, the perception of 'very bad' or 'fairly bad' fell by one percentage point, from 36 % to 35 %. Interference or pressure from government and politicians was the most likely reason for a bad rating of perceived independence of courts and judges ⁽⁹⁾. The opinion about the independence of courts and judges varied significantly across Member States. While in Finland, Denmark and Austria, the majority of respondents (88 %, 84 % and 83 %, respectively) rated the independence of their courts and judges as 'very good' and 'fairly good', this was only the case for 21 % of respondents in Croatia, 24 % in Poland and 25 % in Slovakia ⁽¹⁰⁾.

53 %
of the EU population rated the independence of courts and judges in their country as very or fairly good in 2022

Age, employment status, education and experience with the justice system seem to have a notable effect on the perception of the independence of the justice system. In 2022, 59 % of 15- to 24-year-old respondents

in the EU gave a good rating, compared with 50 % of respondents aged 55 or over. Employees (59 %) were more likely to give a good rating than self-employed people (52 %), manual workers (51 %) or people who were not employed (51 %). The longer people remained in education, the more likely they were to rate the independence of courts and judges as good: 57 % of those who completed education aged 20 or above gave a good rating, compared with 40 % of those who completed education aged 15 or younger. Notably, respondents who had been involved in a dispute that had gone to court were more evenly split between those who rated their system as good (51 %) and bad (45 %) than those who had not been to court (53 % good, 35 % bad) ⁽¹¹⁾.

Trust in institutions

Effective justice systems are a prerequisite for the fight against corruption. Corruption causes social harm, especially when it is instrumentalised by organised crime groups to commit other serious crimes, such as trafficking in drugs and humans. Corruption can undermine trust in democratic institutions and weaken the accountability of political leadership. It also inflicts financial damage by lowering investment levels, hampering the fair operation of the internal market and reducing public finances.

Corruption perception in the EU has stagnated since 2016

Because there is no meaningful way to assess absolute levels of corruption in countries or territories on the basis of hard empirical evidence, capturing the perceptions of those in a position to offer assessments of public-sector corruption is currently the most reliable method of comparing relative corruption levels across countries. According to Transparency International's [Corruption Perceptions Index](#) (CPI), the EU scored 64 on a scale from 0 (highly corrupt) to 100 (very clean) in 2022. This was 21 points more than the world average score of 43. The EU's score has remained stable at this level since 2016, indicating no significant changes in the perception of corruption in Europe.

On a country level, EU countries continued to rank among the least corrupt globally in 2022 and made up more than a half of the top 10 least-corrupt countries globally. Within the EU, northern European countries achieved the best scores, with Denmark, Finland and Sweden leading the ranking. At the other end of the scale, Hungary, Bulgaria and Romania showed the highest levels of perceived corruption across the EU, ranking at positions 77, 72 and 63, respectively, on the global list (comprising 180 countries in total) ⁽¹²⁾.

64
out of 100
was the EU's
Corruption
Perception
Index score in
2022

Country rankings in the CPI largely correspond to analogous answers collected in 2022 through a [Eurobarometer survey](#) ⁽¹³⁾, in which Denmark, Finland and Sweden were identified as having the least corruption. Responses to this survey, however, paint a more pessimistic picture of corruption levels across the EU than the CPI. In all but five countries, at least half of respondents considered corruption to be a widespread national problem. For the EU as a whole, this translates into an average of 68% of respondents sharing this perception in 2022. This share has fallen by 8 percentage points since 2013. On the other hand, the proportion of the population who think corruption in their country is rare reached a high of 28% in 2022.

There is a notable relationship between the CPI and the perceived independence of the justice system. Countries with a high CPI ranking, such as Denmark, Finland or Sweden, also show a high share of the population rating the independence of the justice system as 'good' (see Figures 16.8 and 16.10). Conversely, countries with less optimistic ratings of the justice system's independence also tend to have lower CPI scores, for example Bulgaria and Croatia. As both indicators are based on people's perceptions, however, a causal relationship between the effectiveness of the justice system and the occurrence of corruption cannot be inferred based on these data. Effective justice systems are nevertheless considered to be a prerequisite for fighting corruption ⁽¹⁴⁾.

Trust in EU institutions has been fluctuating over the past few years

Confidence in political institutions is key for effective democracies. On the one hand, citizens' confidence increases the probability that they will vote in democratic elections. On the other hand, it provides politicians and political parties with the necessary mandate to take decisions that are accepted in society.

Trust in three of the EU's main institutions — the European Parliament, the European Commission and the European Central Bank — has experienced periods of growth and decline throughout the past two decades. All three institutions saw a drop in trust in 2020, but data for 2023 indicate they have regained some ground, with 49% of the population expressing confidence in the European Parliament and 46% in both the European Commission and the European Central Bank. Compared with 2022, however, trust in the Commission and the Parliament decreased by 1 percentage point, while trust in the European Central Bank increased by 2 percentage points. Throughout the years, the European Parliament has remained the most trusted of the three institutions surveyed.

49%
of the EU
population
expressed trust
in the European
Parliament in
2023, making
it the most
trusted of
the main EU
institutions

The economic crisis may have played a role in the decline in trust in EU institutions observed between 2007 and 2015, while the COVID-19 pandemic might have influenced the drop in 2020. High inflation levels due to pressure on energy, food and other commodity prices as a result of Russia's aggression against Ukraine might have caused a decline in trust in the European Central Bank in 2022 and in the Commission and Parliament in 2023. However, surveys show that citizens tend to only have a general idea about the EU and lack a deeper knowledge of the role and powers of the EU institutions, making confidence in the EU more dependent on contextual information than on actual governance ⁽¹⁵⁾.

17

Strengthen the means of implementation and revitalise the global partnership for sustainable development

SDG 17 calls for a global partnership for sustainable development. It highlights the importance of macroeconomic stability and of mobilising financial resources for developing countries. It also stresses the importance of trade and equitable rules for governing it. The goal also emphasises the importance of access to science and technology, in particular internet-based information and communications technology.

Partnership is at the essence of the EU and an overarching principle to approach the SDGs within and beyond the EU boundaries. Monitoring SDG 17 in an EU context focuses on global partnership, financial governance, and access to technology. Over the assessed five-year period, the EU's progress in the area of global partnership was mixed. While imports from developing countries have grown, financing to these countries has decreased, and the EU is still behind on its path towards its official development assistance target. Moreover, financial governance within the EU remains a challenge, as exemplified by a falling share of environmental taxes in total tax revenues and high levels of general government gross debt. Meanwhile, access to technology in the EU progressed, with a significant increase in the share of households connected to high-speed internet.

Policy context

Global partnership

The New [European Consensus on Development](#) outlines the need to dedicate a high proportion of official development assistance to least developed countries (LDCs) and other low-income countries. Hence, 0.15–0.20% of GNI should be allocated to LDCs in the short term, rising to 0.20% by 2030.

The [European Fund for Sustainable Development Plus \(EFSD+\)](#) helps mobilise private-sector financing and maintain 'duty free and quota free' market access to LDCs as set out in the [Addis Ababa Action Agenda \(AAAA\)](#).

The EU's '[Generalised Scheme of Preferences](#)' allows developing countries to pay less or no duties on their exports to the EU. The [Everything But Arms](#) arrangement grants duty-free and quota-free access for all LDC products except arms and ammunition. The EU also provides significant amounts of '[aid for trade](#)', with the aim of supporting trade-related infrastructure and building productive capacity.

[Global Gateway](#) is the EU strategy to support partner countries to boost smart, clean and secure links in digital, energy and transport sectors, and to strengthen health, education and research systems.

In 2021, the EU [renewed its Multilateralism Strategy](#) to further the cooperation on global challenges such as peace and security, human rights and the rule of law, sustainable development, public health and climate change.

In 2022, the Commission reaffirmed the EU's commitment to champion decent work both

at home and around the world. As part of this approach, the Commission in 2022 presented a proposal for a regulation to prohibit products made using forced labour, including child labour, on the EU internal market. Also in 2022, the EU reached a provisional agreement on a [Carbon Border Adjustment Mechanism \(CBAM\)](#), a tariff on carbon-intensive imports to encourage cleaner production processes globally.

Financial governance within the EU

The [Treaty on the Functioning of the European Union \(TFEU\)](#) requires a Member State's annual government deficit-to-GDP ratio to not exceed 3%, and that government debt as a ratio of GDP should be limited to 60%. The TFEU is complemented by [Regulation 1176/2011 on the prevention and correction of macroeconomic imbalances](#) as well as [Regulation 1174/2011 on enforcement measures to correct excessive macroeconomic imbalances in the euro area](#).

Access to technology

In the [2020 Digital Strategy](#), the EU committed to developing a Global Digital Cooperation Strategy that will reflect the SDGs.

The [2030 Digital Compass](#) presents a vision for Europe's digital transformation and sets the target of all European households to be covered by a gigabit network by 2030.

The [Declaration on European Digital Rights and Principles](#) calls for equal access to technology and digital literacy education as a fundamental right.

Partnerships for the goals in the EU: overview and key trends

Global partnership

To achieve the SDGs, partnerships are necessary between governments, the private sector, civil society and other parties. Wealthier economies such as the EU can support the implementation of the 2030 Agenda in developing countries through public and private, domestic and international resources. These resources can be both financial and non-financial ⁽¹⁾. This chapter focuses on the former. Overall, the global partnership indicators show a mixed picture for the EU over the past few years.

The EU supports country-led development through a range of financial support mechanisms

In 2015, in the Addis Ababa Action Agenda, all countries recognised that international public finance plays an important role in complementing countries' domestic efforts to mobilise public resources, especially in the poorest and most vulnerable countries. **Official development assistance** (ODA), other official flows (OOFs), private flows, such as **foreign direct investment** (FDI), grants by non-governmental organisations (NGOs) and officially supported export credits ⁽²⁾ are some of the financial flows from the EU and its Member States to developing countries.

Regarding the total volume of financial flows from the EU to developing countries, the Organisation for Economic Co-operation and Development (OECD) estimates that total public and private EU financing to developing countries amounted to EUR 111.3 billion in 2021. When accounting

for inflation, this is about the same level as the financial flows provided by the EU fifteen years earlier, and is – in part substantially – lower than the amounts provided between 2014 and 2019. While OOFs and grants by NGOs have remained rather marginal, ODA and private flows combined have accounted for 95 % or more of total estimated EU financing for development since 2014. Overall, ODA has been the most reliable and steady financial flow from the EU to developing countries, while private flows have varied strongly over the years.

Official development assistance: a long struggle to meet targets

The idea that donor countries should contribute 0.7 % of their **gross national income** (GNI) to ODA has been on the international agenda for half a century. The EU is committed to reaching the 0.7 % target by 2030, as affirmed in the **New European Consensus on Development**. Member States that joined the EU after 2002 have committed to provide 0.33 % of their GNI for ODA. As a whole, the EU spent 0.49 % of its GNI on ODA in 2021, slowly descending from 0.50 % in 2020. The peak of 2020 in the EU's ODA to GNI ratio reflected a global trend, with worldwide ODA having reached an overall high as a result of donor efforts in the context of the COVID-19 pandemic ⁽³⁾. In the EU, the decrease in the ODA to GNI ratio from 2020 to 2021 is a result of GNI growing faster (by 8.6 %) than ODA (by 6.3 %) ⁽⁴⁾.

Only four EU countries – Luxembourg, Sweden, Germany and Denmark – achieved the 0.7 % target in 2021, meaning additional efforts will be needed to meet the collective EU target by 2030.

The EU remains the world's biggest ODA donor

In 2021, the EU maintained its position as the biggest ODA donor globally, providing about EUR 71.6 billion. This figure refers to the combined ODA provided by the 27 EU Member States and EU institutions. Moreover, with 0.49 % in 2021, the EU's overall ODA/GNI ratio was significantly higher than for most other Development Assistance Committee's (DAC) donors such as Canada, Japan or the United States. At the same time, aid from emerging donors is gaining in relevance. For example, Saudi Arabia and Türkiye spent about 1 % of their GNI on ODA in 2021 ⁽⁵⁾.

The EU seeks to support least developed countries in particular

To direct resources where they are most needed — **least developed countries** (LDCs) and countries in states of fragility and conflict — the EU has a target to collectively provide 0.15–0.20 % of GNI to LDCs in the short term, reaching 0.20 % within the timeframe of the 2030 Agenda. In 2021, the EU's collective official development assistance to LDCs accounted for 0.11 % of GNI, following a period of stagnation around this value since 2012. The EU has thus not progressed towards its 0.20 % target over the past few years. In 2021, only three Member States – Luxembourg, Sweden and Denmark – exceeded the targeted GNI ratio of ODA to LDCs. In addition, Finland exceeded the short-term target, with a ratio of 0.16 %.

ODA is only a part of several financing mechanisms

The EU seeks to ensure that developing countries can combine aid, investment and trade with domestic resources and policies to build capacity and become self-reliant. ODA, for example, can be used as a catalyst to mobilise other financial resources such as domestic tax revenues or resources from the private sector. Other innovative instruments have been developed, such as blending grants with loans, guarantees or equity from public and private financiers.

EU financial support, combined with domestic and private revenues, can provide a basis for achieving the 2030 Agenda's goals, allowing for investment in social services, clean energy, infrastructure, transport and information and communications technologies. In the best case, developing countries could leapfrog some of the unsustainable modes of production and consumption that industrialised countries use.

EU imports from developing countries reached a new record high in 2022

Trade's potential contribution to sustainable development has long been acknowledged. This is reflected in the EU's 2021 [Trade Policy Review](#), along with the [European Green Deal](#) which stresses the contribution that trade policy can make to achieving the EU's ambition on sustainable development.

Exports can create domestic jobs and allow developing countries to obtain foreign currency, which they can use to import necessary goods. Better integration of developing countries into world markets may reduce the need for external public flows. Several of the SDGs refer to the importance of trade for sustainable development. However, it needs to be noted that the EU's trade-related indicators do not provide insights on whether the products in question are produced in an environmentally and socially sustainable manner.

Between 2007 and 2022, EU imports from developing countries more than doubled from EUR 617 billion to EUR 1 508 billion. Over this period, EU imports from developing countries grew by 6.1 % per year on average. Over the short term, since 2017, imports have grown even more strongly, by 12.5 % a year. Both trends were largely driven by a considerable increase in imports from developing countries by almost 40 % in 2022 compared with 2021.

1 508
billion EUR
was the value of
EU imports from
developing
countries in
2022

Growth was particularly strong for least-developed countries, whose imports increased by more than 84 % from 2021 to 2022.

Imports from developing countries to the EU as a share of imports from all countries outside the EU increased from 43.2 % in 2007 to 50.2 % in 2022. Similar to 2021, developing countries (including China) thus accounted for half of all extra-EU imports in 2022. China (excluding Hong Kong) alone accounted for 20.9 % of EU imports in 2022. This is almost twice the share of imports from the United States, which accounted for 11.9 %. Conversely, the almost 50 countries classified as least developed by the UN accounted for just over 2 % of all EU imports in 2022 ⁽⁶⁾.

'Aid for trade' is a part of ODA that is targeted at trade-related projects and programmes. It aims to build trade capacity and infrastructure in developing countries, particularly least developed countries. The EU and its Member States were the leading global providers of aid for trade in 2020, providing EUR 23 billion, or 47 % of global aid for trade. Just three donors — the EU institutions as well as Germany and France — provided 90 % of this overall sum. The share of aid for trade to LDCs was 13 % of overall aid for trade in 2020, two percentage points lower than in the three years before ⁽⁷⁾.

Financial governance within the EU

To help other countries to advance their economies, the EU's own economies must also remain on a sustainable development path. Macroeconomic stability in the EU is therefore one pillar of the Union's contribution to implementing the SDGs. In addition, the EU seeks to make its economy greener. In a global context, where consumption patterns in one region can severely impact production patterns elsewhere, it is particularly important that prices reflect the real costs of consumption and production. They should include payments for negative externalities caused by polluting activities or other activities that damage human health and the environment. Moreover, the EU has pointed out

that environmental taxes may offer opportunities to reduced taxes in other areas, for example on labour.

Steady progress in reducing government debt as a share of GDP was halted by the COVID-19 pandemic

According to the Treaty on the Functioning of the European Union, [government debt](#) should not exceed 60 % of GDP in EU Member States. As a consequence of the COVID-19 crisis and related public spending, the EU's overall debt-to-GDP ratio rose sharply in 2020 to reach 90.0 %, which is a 12.3 percentage point increase compared with 2019. In 2021 and 2022, the EU's debt-to-GDP ratio fell by 2.0 and 4.0 percentage points compared with the previous year, respectively. In 2022, the ratio thus stood at 84.0 %, which is 2.1 percentage points higher than five years earlier.

In 2022, Member States' debt-to-GDP ratios ranged from 18.4 % in Estonia to 171.3 % in Greece. Thirteen EU countries exceeded the 60 % threshold in 2022 and six Member States had debt-to-GDP ratios above 100 %.

In 2022, general government gross debt in the EU as a share of GDP was **84.0 %**

'Greening' the taxation system remains a challenge

[Environmental taxes](#) help to provide the right price signals and incentives to producers, users and consumers to encourage less polluting consumption and to contribute to sustainable growth. They may also provide opportunities to reduce taxes in other areas, for example on labour, and if revenue for adequate social protection is protected, they can offer a win-win option for addressing both environmental and employment issues, as laid out in the EU's [Action Plan for Fair and Simple Taxation](#). Environmental taxes support the transition to a climate-neutral economy ⁽⁸⁾. As indicated in the [Communication on Business taxation for the 21st century](#) as regards the EU tax

mix, behavioural taxes, such as environmental and health taxes, continue to be of growing importance for EU tax policies. Well-designed environmental taxes help to support the green transition by sending the right price signals, as well as implementing the polluter pays principle. They also generate revenue that could compensate some of the needed labour tax cuts.

In 2021, environmental taxes accounted for only 5.5 % of total tax revenues in the EU, while labour taxes accounted for 53.5 % in 2020 ⁽⁹⁾. Energy taxes constituted the main part of environmental taxes, accounting for 4.3 % of tax revenues in 2021, followed by transport taxes with a share of 1.0 %. In comparison, taxes on pollution and resources – the third component of environmental taxes – remained negligible, accounting for only 0.2 % of total tax revenues in 2021 ⁽¹⁰⁾. The share of total environmental taxes has fallen considerably since 2016 in parallel to an increase in the share of labour taxes, meaning that in the EU the tax burden is shifting from environment to labour instead of the other way round. Across Member States, the share of environmental taxes in total tax revenues ranged from 3.8 % in Luxembourg to 10.0 % in Greece in 2021. Compared with 2016, their share has further decreased in almost all EU countries. Only Greece — the country with the highest share of environmental taxes in 2021 — reported a 0.2 percentage point increase over this period.

The ratio of labour to environmental taxes shows how much higher a country's share of labour tax revenues is than its share of environmental taxes. In 2020, this ratio ranged from 3.8 to 14.0 across Member States. The ratio has also increased in the majority of countries since 2015, indicating a relative shift in taxation from environment to labour across the EU.

In 2021, the share of environmental taxes in total tax revenues in the EU was 5.5%

EU Member States spend on average 2 % of their GDP to protect the natural environment

The decline in the prioritisation of environmental taxation is partly reflected in national environmental expenditures. National expenditure on environmental protection measures the amount of resources a country uses to protect the natural environment. It includes current expenditure on environmental protection activities, investments in these activities and net transfers to other parts of the world.

At EU level, environmental protection expenditure has stagnated at about 2 % of GDP since 2010, amounting to EUR 292 billion in 2021. Across EU Member States, in 2019 expenditure ranged from 3.5 % of GDP in Austria to 0.7 % in Ireland. In the majority of Member States, these shares have decreased or remained stable since 2014. Only seven countries increased their environmental protection expenditure relative to GDP between 2014 and 2019, with the strongest growth reported by Poland (1.0 percentage points increase) and Austria (0.4 percentage points) ⁽¹¹⁾.

Access to technology

In today's economies and societies, digital connections are crucial. Instant communication between individuals, bank transfers, office work, public dissemination of information and data analysis are only some of the activities that depend on the internet. Regions without fast internet connections have serious social and economic disadvantages in a digitalised world. As a result, making Europe fit for the digital age is one of the six Commission priorities for 2019 to 2024. The aim is to make the digital transformation work for people and businesses while helping to achieve the target of a climate-neutral Europe by 2050.

Considerable progress has been made in rolling out high-speed internet coverage across the EU

Data collected by the European Commission services for the [key dimensions of the European information society](#) ⁽¹²⁾ shows that in the EU the uptake of high-speed internet coverage — referring to fibre connections or other networks offering similar bandwidth — has improved considerably over the past few years. While only 25.2 % of EU households enjoyed such connectivity in 2016, this

70.2%
of EU
households
had high-
speed internet
coverage in
2021

share has risen considerably, reaching 70.2 % in 2021. If high-speed internet roll-out continues at this pace, the EU will reach 100 % coverage well ahead of 2030. Connectivity has also improved in rural areas ⁽¹³⁾. Between 2016 and 2021, the share of rural households with fixed high-speed internet connection increased from 7.7 % to 37.1 % across the EU.

At Member State level, Malta had already achieved a 100 % fixed high-speed internet connectivity for all households in 2021, followed by Luxembourg, Denmark and Spain with around 95 % of households each. In contrast, fixed high-speed internet connections were the least widespread in Greece, with only 19.8 % of households enjoying such connectivity. All remaining Member States had connection rates to high-speed internet above 40 % in 2021.

Overview of status and progress of EU Member States towards the SDGs

This chapter presents a statistical overview of the status and progress of EU Member States towards the 17 SDGs, based on the EU SDG indicator set. The status of each SDG in a Member State is an aggregation of all the indicators of a specific goal relative to the other Member States and the EU average. The progress score of the Member State is based on the average annual growth rates of all assessed indicators in the SDG over the past five years. The same approach towards aggregating individual indicator trends into a synthesised index per SDG is used in the synopsis chapter for the EU ⁽¹⁾.

Such a synthesised presentation allows for a quick and easy overview and facilitates communication. However, applied to individual Member States, it entails the risk of simplification and might obscure details about underlying phenomena. Moreover, it has to be kept in mind that a country's status depends to a certain extent on its natural conditions and historical developments. Therefore, users are invited to read the more detailed information at indicator level in the chapters 1 to 17 on each SDG. Detailed data for the EU SDG indicators on a country level are also available on the [Eurostat website](#), for example in the [key findings](#) section and in the [country overview visualisation](#).

How is the status and progress assessed?

The status of a specific SDG is an aggregate score encompassing all indicators of that goal, based on the most recent data (mainly referring to 2021

and 2022) ⁽²⁾. For each indicator, a country's status score is calculated relative to the range of values from the worst to the best performing country, whereby outliers are excluded ⁽³⁾. The status score calculation is based on a min-max-normalisation as described in Annex I. For each country, the status scores at indicator level are aggregated at SDG level using the arithmetic mean, and this goal-level score is then put in relation to the EU aggregate status score of the same goal, to show how much (in %) a country's SDG status is above or below the EU average. Figure 18.1 presents an example of the calculation of the status score for SDG 16 relative to the EU for a fictitious country.

Progress is an aggregate score of the short-term (five-year) growth rates for all the indicators assessed for each goal. The methodology uses a scoring function and is identical to the calculation of progress at EU level as presented in Annex I. Please note that the progress score calculation does not take into account any target values, since most EU policy targets are only valid for the aggregate EU level. Data mainly refer to the periods 2016–2021 or 2017–2022. Due to data availability issues, such as missing data for some years or breaks in time series, some countries' progress score calculations are based on shorter or longer periods. Additionally, some countries' progress scores have been manually adjusted, for example when a country has already achieved the maximum possible value (for example, 100 % of young children participating in early childhood education) and has maintained this level over the past five-year period. In such cases, countries are assigned the best possible score (+5) instead of the
